Parastrophic-orthogonal quasigroups

Valentin D. Belousov

Abstract

The notion of orthogonality plays an important role in the theory of Latin squares, and consequently also in the theory of quasigroups, because every finite quasigroup has a Latin square as its Cayley table and, conversely, every Latin square is the multiplication table of a certain quasigroup.

The concept of orthogonality can be described very easily in algebraic language. Two quasigroups $Q(A), Q(B)$ (i.e. quasigroups with operations $A$ and $B$ defined on the same set $Q$) are orthogonal if the system of equations $A(x, y) = a, B(x, y) = b$ has a unique solution for every pair of elements $a, b \in Q$.

There is significant interest in the investigation of quasigroups orthogonal to their parastrophes (for the definitions see below). However, in the past, the questions mainly considered have been some combinatorial ones which have arisen in connection with these investigations. We mention, for example, the Phelps papers (for example [6]) which are devoted to the study of the spectrum of $\alpha$-orthogonal quasigroups, i.e. quasigroups $A$ which are orthogonal to their parastrophe $\mathcal{A}$.

Special cases of such quasigroups were considered earlier in connection with other problems having purely algebraic character. For example, Stein

2000 Mathematics Subject Classification: 20N15, 20N05
Keywords: Quasigroup, parastrophe, orthogonality
studied quasigroups with the identity $x \cdot xy = yx$. It is easy to see that such a quasigroup $Q(\cdot)$ is orthogonal to its parastrophe $Q(*)$, where $x \ast y = yx$.

Indeed, let us consider the system of equations $xy = a$, $yx = b$. If there exists a solution then, by the identity $x \cdot xy = yx$, it must be $xa = b$, whence we obtain $x$ uniquely: $x = b/a$. The element $y$ also is uniquely determined: $y = x \setminus a = (b/a) \setminus a$. In this way, if a solution exists, it is uniquely determined. It remains to show that the obtained values of $x$, $y$ satisfy the given system of equations. We have $xy = (b/a)((b/a) \setminus a) = a$, because in the quasigroup $Q(\cdot)$ the basic identity $x(x \setminus y) = y$ is satisfied. Further we have $yx = [(b/a) \setminus a](b/a)$. Let $b/a = c$, $c \setminus a = d$, then $b = ca$, $a = cd$ and $yx = dc$. But $b = ca = c \cdot cd = dc$, by the Stein identity. Therefore $yx = dc = b$.

Thus, from the fact that the above identity holds in a quasigroup $Q(\cdot)$, it follows that a pair of orthogonal parastrophes is related to this quasigroup.

As will be shown below, other identities also have this property: that is, they imply the existence of orthogonal parastrophes. Such identities, in particular ones which are minimal in some sense, will be completely described. It will be shown that, up to a certain kind of equivalence, there are exactly seven types of such identities (including the Stein identity mentioned above).

Of course, it would be important to give a description of the seven types of quasigroup obtained, i.e. a description of loops isotopic to them. But a search for such a description of isotopic loops was unsuccessful because these quasigroups are defined by identities containing only two variables. Nevertheless, if we make the assumption that quasigroups satisfying the minimal identities are isotopic to groups, then we can obtain some additional information about such groups.

§0. Necessary preliminaries from the theory of quasigroups

1°. The set $Q$ with one binary operation $(\cdot)$ is called a quasigroup if the equations $ax = b$, $ya = b$ have unique solutions for all $a, b \in Q$. A quasigroup with an identity, i.e. with an element $e$ such that $ae = ea = a$ for all $a \in Q$, is called a loop. We shall denote quasigroups and loops by $Q(\cdot)$ or, if the operation is denoted as a function, say $A(a, b) = c$, by $Q(A)$. Also the operations $(\cdot)$ and $A$ will be called quasigroups (or loops).

2°. A quasigroup $(\circ)$ is isotopic to a quasigroup $(\cdot)$, where $(\circ)$ and $(\cdot)$
are defined on the same set \( Q \), if there exists a triplet \( T = (\alpha, \beta, \gamma) \) of permutations of the set \( Q \) such that \( x \circ y = \gamma^{-1}(\alpha x \cdot \beta y) \). The relation of isotopy determines an equivalence on the set of all quasigroups defined on the set \( Q \).

3°. Let \( Q(\cdot) \) be a quasigroup, \( L_a : x \rightarrow ax \), \( R_a : x \rightarrow xa \). The mappings \( L_a, R_a \) are permutations of the set \( Q \). The isotope \( Q(\circ) \), where \( x \circ y = R_a^{-1}x \cdot L_b^{-1}y \), of the quasigroup \( Q(\cdot) \) is a loop with the identity \( ba \).

4°. Let \( Q(\cdot) \) be a quasigroup. The solution of the equation \( ax = b \) is denoted by \( x = a \setminus b \) and the solution of the equation \( ya = b \) by \( y = b/a \).

The operations so defined are called inverses of \((\cdot)\), or, more precisely, the right (respectively, left) division for \((\cdot)\). The operations \((\setminus)\) and \((/\) also define quasigroups. If a quasigroup is denoted by \( A \), then the operations of right and left division will be denoted by \( A^{-1} \) and \( \overline{A} \), respectively. The latter operations also have inverses: \( (A^{-1})^{-1} = A \), \( (-A)^{-1} \).

Moreover, one can consider the operations \( [-1(A^{-1})]^{-1} \), \( -1[(-A)^{-1}] \), but these operations are identical with \( A^* \), where \( A^*(x, y) = A(y, x) \).

The following equalities are equivalent:

\[ A(x, y) = z \quad \iff \quad A^{-1}(x, z) = y \iff \quad -A(z, y) = x \iff \quad -1(A^{-1})(y, z) = x \iff \quad (-1A)^{−1}(z, x) = y \iff \quad A^*(y, x) = A(x, y). \]

In what follows, we shall use the following notations for cycles: \((12) = s, (13) = t, (23) = r\). The cycles \( l, r \) generate the group \( S_3 \). Moreover, we have \( rlr = lrl = s \). Thus \( A^{-1} = rA, \overline{A}^{-1} = lA, A^* = sA \).

5°. The operations \( A, A^{-1}, -A, \overline{A}, -1(A^{-1}), (-A)^{-1}, A^* \) are called the parastrophes of the operation \( A \). Parastrophes of a quasigroup \( A \) are frequently denoted by \( \sigma A \), where \( \sigma \in S_3 \) - the symmetric group of degree 3.

More exactly, we have the equivalences:

\[ \sigma A(x', y') = z' \quad \iff \quad A(x, y) = z, \]

1Editors’ Note: These operations have also been called conjugates of the operation \( A \) by other authors, especially in the U.S.A. The word parastrophe dates back to 1915 and was used by Sade(1939)[14] and Artzy(1963)[9] before its adoption by Belousov. The name “conjugate” seems to have originated with Stein in the 1950s and was used in [8]. It has the disadvantage that its use in the present context conflicts with its more usual meaning in the context of group and loop theory for describing equivalence relative to inner automorphisms. [The reader should note that footnotes labelled \( a, b, \ldots \) were in the original Russian text and in the English version sent to Keedwell by Belousov himself but footnotes numbered 1, 2, ... have been inserted by the Editors.]
where \((x', y', z') = \sigma(x, y, z)\). For example, \(-1(A^{-1}) = \sigma A\), where \(\alpha(x, y, z) = (y, z, x)\), i.e. \(\alpha = (1\ 2\ 3)\).

The relations:

\[
\tau(\sigma A) = \tau A, \quad B = \sigma A \iff A = \sigma^{-1}B
\]

hold for the parastrophes.

6\textsuperscript{0}. The quasigroup operation \((\cdot)\) and its inverses \((\setminus)\) and \((/\ )\) are interconnected by the following identities:

\[
\begin{align*}
x(x \setminus y) & = y, \quad x \setminus(xy) = y, \\
(y/x)x & = y, \quad (yx)/x = y.
\end{align*}
\]

The quasigroup \(Q(\cdot)\) can be considered as a universal algebra \(Q(\cdot, \setminus, / )\).

7\textsuperscript{0}. Two operations \(A\) and \(B\) (not necessarily quasigroup operations), defined on the set \(Q\), are orthogonal if the system of equations

\[
A(x, y) = a, \quad B(x, y) = b
\]

is uniquely soluble for all \(a, b \in Q\). We use the notation \(A \perp B\) to express this. It is clear that \(A \perp B\) implies \(B \perp A\).

8\textsuperscript{0}. If \(\bar{\varphi}\) is a mapping of the set \(Q^2\) into itself, then there are two operations \(C, D\) such that \(\bar{\varphi}(x, y) = (C(x, y), D(x, y))\). The mapping \(\bar{\varphi}\) is a permutation if and only if \(C \perp D\). The mapping \(\bar{\varphi}\) is denoted by \((C, D)\): \(\bar{\varphi} = (C, D)\).

The pair of operations \(C, D\) is uniquely determined by the mapping \(\bar{\varphi}\). The following theorem is valid (see [2]): if \(A \perp B\), where \(A, B\) are quasigroup operations, and \(\bar{\theta} = (A, B)\), then the inverse permutation \(\bar{\theta}^{-1}\) has the form \(\bar{\theta}^{-1} = (A', B')\), where \(A'\) and \(B'\) are also quasigroup operations.

The identity permutation \(\bar{\varepsilon}\) on \(Q^2\) defines a pair \(F, E\) of operations on \(Q\) such that \(F(a, b) = a, \quad E(a, b) = b\) for all \(a, b \in Q\); that is, \(\bar{\varepsilon} = (F, E)\).

If \(\bar{\varphi}, \bar{\psi}\) are two permutations on the set \(Q^2\), then, by definition, \((A \bar{\varphi}) \bar{\psi} = A(\bar{\varphi} \bar{\psi})\), and \((A, B)\bar{\varphi} = (A \bar{\varphi}, B \bar{\varphi})\) for all \(A, B, \bar{\varphi}, \bar{\psi}\). Also, by definition, we have \((A \bar{\varphi})(x, y) = A(\bar{\varphi}(x, y))\).

9\textsuperscript{0}. A system \(\Sigma = \{A_1, A_2, \ldots, A_k\}\) is called an orthogonal system of quasigroups (or, for brevity, an OSQ), if

1) \(A_i \perp A_j\) for all \(i, j \in \{1, 2, \ldots, k\}, i \neq j\), and
2) \(A_1 = F, \quad A_2 = E\).

We remark that the operations \(\{A_3, A_4, \ldots, A_k\}\) must be quasigroups because \(A \perp E\) and \(A \perp F\) imply that \(A\) is a quasigroup.
§1. Minimal identities and connections with orthogonalities

Let us consider the algebra $Q(\Sigma)$, where $\Sigma$ is some system of quasigroup operations (quasigroups) defined on the set $Q$, and let $w_1 = w_2$ be an identity in $Q(\Sigma)$. We denote the number of free elements in the word $w$ by $|w|$. Let $l = |w_1| + |w_2|$.

Now, we shall determine all non trivial identities in $Q(\Sigma)$ having the minimal length $l$.

The identity $w_1 = w_2$ will be called nontrivial, if

a) there is no subword of the form $A(u, u)$ (no "square"),

b) there are no isolated free elements.

The first condition can be justified by remarking that $A(u, u)$ can be replaced by $au$, i.e. by a unary operation, but we are considering only binary operations. The second condition is also reasonable: the identity $w_1 = w_2$ with an isolated element $z$ (that is, in $w_1 = w_2$, the element $z$ occurs only once) can be transformed to the form $w' = z$. Then, by fixing all elements in $w'$, we get $w' = z_1$, $w' = z_2$, where $z_1$, $z_2$ are arbitrary elements of $Q$, i.e. $z_1 = z_2$, whence we obtain that $Q$ has only one element.

Let us determine the minimal $l$. It is clear that $l \geq 3$. If $l = 3$, then the identity $w_1 = w_2$ is trivial, since the condition a) or b) is violated. If $l = 4$, then the identity $w_1 = w_2$ contains two free elements $x$, $y$ exactly twice, otherwise condition a) or b) does not hold. In this case, the identity has the form $A(x, (B(x, y)) = y$ or $A(x, y) = B(x, y)$. It appears that the identity might also have the form $A(B(x, y), x) = y$ for example but, by replacing $A$ by its parastrophe $A^*$ in this instance, we obtain $A^*(x, B(x, y)) = y$, which is an identity of the first type. Similar arguments can be used for other cases. But these two identities are also trivial, because the first determines the right inverse operation $B = A^{-1}$ and the second implies that $A = B$.

Thus, the minimal length $l$ of a nontrivial identity $w_1 = w_2$ must be equal to 5 (at least). If $l = 5$, the identity $w_1 = w_2$ contains only two free elements $x$, $y$. More than three free elements is not possible because the condition b) would be violated. If the identity contains exactly three free elements $x, y, z$ then, as is easy to see, the condition b) is violated in that case too.

Therefore the identity $w_1 = w_2$ (if of length 5) contains only two free elements $x, y$ and one of them, say $x$, is contained in it three times and the other twice, otherwise the condition b) would be violated.

With the help of transformations to inverse operations where necessary, the identity $w_1 = w_2$ can be transformed to the form $w' = y$, where $w'$
contains the element $x$ three times and $y$ just once. The identity $w' = y$ might have, a priori, any one of the following forms:

1. $A(z_1, B(z_2, C(z_3, z_4))) = y,$

2. $A(z_1, B(C(z_2, z_3), z_4)) = y,$

3. $A(B(z_1, z_2), C(z_3, z_4)) = y,$

4. $A(B(C(z_1, z_2), z_3), z_4) = y,$

5. $A(B(z_1, C(z_2, z_3)), z_4) = y.$

We see immediately that the identity $w' = y$ cannot have the form 3 because, by condition a), one of $z_1$ or $z_2$ must be $y$ and, likewise, one of $z_3$ or $z_4$ must be $y$ but then $y$ would occur in $w' = y$ three times, which contradicts the assumption that $y$ occurs only twice.

Further we can remark that, with the aid of the transformation $K \to K^*,$ we can transform the identities 2, 4, and 5 to the form 1. For example, in the case of 5 we get $A^*(z_4, B(z_1, C(z_2, z_3))) = y.$ Next, let us consider the identity 1. It is evident that either $z_3$ or $z_4$ must be $y.$ Let $z_4 = y$ (if $z_3 = y,$ we replace $C$ by $C^*.$) The remaining elements are equal to $x:$ $z_1 = z_2 = z_3 = x.$ Thus, any nontrivial minimal identity of the algebra $Q(\Sigma)$ can be transformed into the form:

$$A(x, B(x, C(x, y))) = y. \hspace{1cm} (1.1)$$

For example, suppose that a nontrivial minimal identity of the form

$$A(B(x, y), C(x, y)) = x. \hspace{1cm} (1.2)$$

is given. We transform it to

$$-1 A(x, C(x, y)) = B(x, y).$$

Let $B(x, y) = z,$ whence $y = B^{-1}(x, z).$ Consequently, we can write

$$-1 A(x, C(x, B^{-1}(x, z))) = z,$$

i.e. (1.2) is transformed to the form of (1.1).

Using multiplication of operations, the identity (1.1) can be rewritten in abbreviated form as

$$ABC = E, \hspace{1cm} (1.3)$$

where $E(x, y) = y$ for all $x, y \in Q.$
Remark 1. It is easy\textsuperscript{2} to deduce that the following equalities are equivalent to (1.3):

\[ BCA = E, \quad (1.4) \]
\[ CAB = E, \quad (1.5) \]
\[ C^{-1}B^{-1}A^{-1} = E, \quad (1.6) \]
\[ B^{-1}A^{-1}C^{-1} = E, \quad (1.7) \]
\[ A^{-1}C^{-1}B^{-1} = E. \quad (1.8) \]

Remark 2. If \( A, B, C \) are quasigroups satisfying (1.3) then the following conditions must be satisfied\textsuperscript{3}:

\[ B \neq A^{-1}, \quad C \neq B^{-1}, \quad A \neq C^{-1}. \quad (1.9) \]

Orthogonality. II-quasigroups.

The orthogonality of operations is closely connected with minimal nontrivial identities. This assertion follows from the following lemma.

Lemma 1. Let \( A, B \) be quasigroups. Then \( A \perp B \) if and only if there exists a quasigroup \( K \) such that \( KBA^{-1} = E \).

Proof. Necessity. Let \( A \perp B \), then \( \bar{\theta} = (A, B) \) is a permutation. Consequently, \( \bar{\theta}^{-1} \) also is a permutation. If \( \bar{\theta}^{-1} = (C, D) \), then \( C \) and \( D \) are quasigroups (see §0 of §0) and

\[ \bar{\theta}^{-1} \bar{\theta} = (C, D)(A, B) = (C(A, B), D(A, B)) = (F, E) = \bar{\varepsilon} \]

(\( \bar{\varepsilon} \) is the identity permutation of \( Q \)). Consequently, \( C(A, B) = F \), i.e. \( C(A(x, y), B(x, y)) = x \). Hence we get \( ^{-1}C(x, B(x, y)) = A(x, y) = z \).

From this we can obtain \( y \): namely, \( y = A^{-1}(x, z) \) and in consequence \( ^{-1}C(x, B(x, A^{-1}(x, z))) = z \) or, briefly, \( ^{-1}CBA^{-1} = E \), i.e. \( K = ^{-1}C \).

Sufficiency. Let \( KBA^{-1} = E \), where \( K \) is a quasigroup. We show that

\[ x_0 = ^{-1}K(a, b), \quad y_0 = A^{-1}(-1K(a, b), a) \quad (1.10) \]

\textsuperscript{2}Editors' Note: For example, \( A(x, B(x, C(x, y))) = y \rightarrow C(x, A(x, B(x, C(x, y)))) = C(x, y) \rightarrow B(x, C(x, A(x, B(x, C(x, y))))) = B(x, C(x, y)) \) or \( B(x, C(x, A(x, z))) = z \), which is (1.4). Also \( A(x, B(x, C(x, y))) = y \rightarrow ^{-1}A(x, y) = B(x, C(x, y)) \rightarrow C(x, y) = ^{-1}B(x, A(x, y)) \rightarrow ^{-1}C(x, B(x, ^{-1}A(x, y))) = y \), which is (1.6).

\textsuperscript{3}Suppose that \( B = A^{-1} \) in (1.4). Then \( A(x, A^{-1}(x, C(x, y))) = y \). Let \( A^{-1}(x, C(x, y)) = z \). Then \( A(x, z) = C(x, y) \) by definition of \( A^{-1} \). But this contradicts \( A(x, z) = y \) which is the given equality.
is a solution of the system of equations $A(x, y) = a, B(x, y) = b$.

Indeed, we have

\[ A(x_0, y_0) = A(-1K(a, b), A^{-1}(-1K(a, b), a)) \]
\[ = AA^{-1}(-1K(a, b), a) = E(-1K(a, b), a) = a, \]
\[ B(x_0, y_0) = B(x_0, A^{-1}(x_0, a)) = BA^{-1}(x_0, a) = d. \]

Then

\[ K(x_0, d) = K(x_0, BA^{-1}(x_0, a)) = KBA^{-1}(x_0, a) = E(x_0, a) = a. \quad (1.11) \]

But from the first equality of (1.10) it follows that $K(x_0, b) = a$. Comparing this with (1.11), we obtain $d = b$ so $B(x_0, y_0) = b$.

Thus, the solution exists. Finally, we show the uniqueness of this solution. Let $x_1, y_1$ be a second pair of solutions so that $A(x_1, y_1) = a$, $B(x_1, y_1) = b$. Then $B(x_1, y_1) = B(x_1, A^{-1}(x_1, a)) = BA^{-1}(x_1, a) = b$.

Hence it follows that $K(x_1, BA^{-1}(x_1, a)) = K(x_1, b)$, or

\[ KBA^{-1}(x_1, a) = K(x_1, b), \]

so $a = K(x_1, b)$ since $KBA^{-1} = E$, whence $x_1 = -1K(a, b)$.

This together with (1.10) implies that $x_1 = x_0$. Now it follows easily that $y_1 = y_0$. Indeed, $y_1 = A^{-1}(x_1, a) = A^{-1}(x_0, a) = y_0$, because $A(x_0, y_0) = a$. Consequently $y_1 = y_0$. \hfill \Box

Next, by writing the equality (1.3) in the form $AB(C^{-1})^{-1} = E$, we conclude that $B \perp C^{-1}$. From (1.4) and (1.5), we deduce that $C \perp A^{-1}$, $A \perp B^{-1}$ so we have the following lemma.

**Lemma 2.** If, in the system $Q(\Sigma)$, the minimal nontrivial identity $ABC = E$ holds, then $A \perp B^{-1}$, $B \perp C^{-1}$, $C \perp A^{-1}$. \hfill \Box

**Minimal nontrivial identities in quasigroups.**

Suppose that a quasigroup $Q(\cdot)$ is given. It can be considered as an algebra $Q(\cdot, \setminus, /)$, $(\cdot) = A$. Of course, a minimal nontrivial identity can be satisfied in a single quasigroup too. It will take the form

\[ ^{\alpha}A^{\beta}A = E, \]

where $\alpha, \beta, \gamma \in S_3$. 

We make the following definition:

**Definition 1.** A quasigroup $A$ is called a **Π-quasigroup of type** $[\alpha, \beta, \gamma]$ if it satisfies the identity $\alpha \beta \gamma \alpha = E$.

**Remark 3.** By virtue of the identities (1.4) - (1.8), the quasigroup $A$ also has the following types: $[\beta, \gamma, \alpha]$, $[\gamma, \alpha, \beta]$, $[r\alpha, r\beta, r\beta]$, $[r\beta, r\alpha, r\beta]$, $[r\alpha, r\gamma, r\beta]$.

**Remark 4.** In view of (1.9), a Π-quasigroup $A$ satisfies the following inequalities: $\beta \neq (\gamma \alpha)^{-1}$, $\gamma \neq (\beta \alpha)^{-1}$, $\alpha \neq (\gamma \beta)^{-1}$ or $\beta \neq r\alpha$, $\gamma \neq r\beta$, $\alpha \neq r\gamma$.

By applying Lemma 2 to a Π-quasigroup $A$ of type $[\alpha, \beta, \gamma]$, we obtain

$\alpha \gamma \beta \alpha$, $\beta \gamma \alpha \beta$, $\gamma \alpha \beta \gamma$.

We shall use the notation

$\alpha \vartriangleleft \beta (A)$

if $\alpha \vartriangleleft \beta$. In what follows, we shall write $\alpha \vartriangleleft \beta$ instead of (1.13) if the relevant quasigroup operation $A$ is clear from the context. Thus a Π-quasigroup $A$ of type $[\alpha, \beta, \gamma]$ will satisfy the following orthogonality relations:

$\alpha \vartriangleleft \beta r\gamma$, $\beta \vartriangleleft \alpha r\alpha$, $\gamma \vartriangleleft \alpha r\beta$.

In the sequel, we shall write $\alpha \vartriangleleft \beta (\sigma)$ instead of $\alpha \vartriangleleft \beta (\gamma A)$. It is evident that

$\alpha \vartriangleleft \beta (\sigma) \leftrightarrow \alpha \sigma \vartriangleleft \beta \sigma$.

Indeed, $\alpha \vartriangleleft \beta (\sigma)$ means that $\alpha (\gamma A) \vartriangleleft \beta (\gamma A)$ or $\alpha \gamma A \vartriangleleft \beta \gamma A$, that is, $\alpha \sigma \vartriangleleft \beta \sigma$.

**Parastrophic equivalence**.

Let us consider the following two transformations of the type of a Π-quasigroup:

$f[\alpha, \beta, \gamma] = [\beta, \gamma, \alpha]$, $h[\alpha, \beta, \gamma] = [r\gamma, r\beta, r\alpha]$.

---

4 Both the original Russian text and (in some places) Belousov’s English translation of it have been modified in this section particularly so as to make the meaning clear.

5 These are admissible because of Remark 3.
It is easy to see that \( f^3 = 1, \quad h^2 = 1 \). Moreover, we have \( fh = hf^2 \). Indeed,
\[
fh[\alpha, \beta, \gamma] = f[r\gamma, r\beta, r\alpha] = [r\beta, r\alpha, r\gamma] = h[\gamma, \alpha, \beta] = hf^2[\alpha, \beta, \gamma].
\]
Thus, the transformations \( f \) and \( h \) generate the group
\[
S^0 = \{1, f, f^2, h, fh, f^2h\},
\]
which is isomorphic to \( S_3 \).

We remark now that, if \( A \) has the type \([\alpha, \beta, \gamma]\), then \(^gA\) has the type \([\alpha\sigma^{-1}, \beta\sigma^{-1}, \gamma\sigma^{-1}]\). This fact suggests making the next definition which has the effect of defining a transformation of the type \([\alpha, \beta, \gamma]\):
\[
[\alpha, \beta, \gamma] \theta = [\alpha\theta, \beta\theta, \gamma\theta] \quad (1.15)
\]
Thus, the preceding remark implies that \(^gA\) has the type \([\alpha, \beta, \gamma]\), when \( A \) has the type \([\alpha\theta, \beta\theta, \gamma\theta]\). The equality (1.15) implies also that if some minimal nontrivial identity is satisfied in \( Q(A) \), then some minimal nontrivial identity holds for each parastrophe also which is related to the preceding one by (1.15). If \( T = [\alpha, \beta, \gamma] \) is the type of a quasigroup \( A \), then we can apply the transformations (1.14) and (1.15) to \( T \) to obtain a relation of the form \( T' = (gT)\theta \), where \( g \in S^0 \), \( \theta \in S_3 \). It is clear that \((gT)\theta = g(T\theta)\), therefore we shall write \( T' = gT\theta \).

**Definition 2.** \( \Pi \)-quasigroups \( B \) and \( A \) are called parastrophically equivalent if their types \( T' \) and \( T \) are connected by a relation of the form \( T' = gT\theta \) for some \( g \in S^0 \) and \( \theta \in S_3 \). Notation: \( T' \sim T \) and \( B \sim A \). We shall also say that the types \( T' \) and \( T \) are parastrophically equivalent.

It is easy to see that parastrophic equivalence is in fact an equivalence relation.

**Remark** to Definition 2. Parastrophic equivalence means that if some minimal identity of type \( T \) is satisfied in a \( \Pi \)-quasigroup \( A \), then a well-defined minimal nontrivial identity of type \( T' = gT\theta \) is satisfied in its parastrophe.\(^6\)

To determine the equivalence classes under parastrophic equivalence, we look for representatives of these classes. Because \( T = [\alpha, \beta, \gamma] = \)

\(^6\)An earlier investigation of this idea was made by A. Sade. See [14] or page 66 of [4]. The concept was also defined (using the name *conjugate-equivalent*) by T. Evans, see page 46 of [13].
Parastrophic-orthogonal quasigroups

[1, \beta \alpha^{-1}, \gamma \alpha^{-1}] \alpha, it follows that $T \sim [1, \sigma, \tau]$, where $\sigma = \beta \alpha^{-1}$, $\tau = \gamma \alpha^{-1}$. Thus the class representatives should have the form $[1, \sigma, \tau]$. Moreover, the conditions (1.12) must be satisfied, namely:

$$\sigma \neq r1, \quad \tau \neq rs, \quad 1 \neq r\tau,$$

That is,

$$(1.16) \quad \sigma \neq r, \quad \tau \neq r, \quad \tau \neq rs.$$ 

First, we consider the case $\sigma = 1$, i.e. we consider the type of the form $[1, 1, \tau]$. The conditions (1.16) become

$$1 \neq r, \quad \tau \neq r, \quad \tau \neq rs,$$

so they reduce to $\tau \neq r$. Thus, we can choose the types

$T_1 = [1, 1, 1], \quad T_2 = [1, 1, l], \quad T_3 = [1, 1, rl], \quad T_4 = [1, 1, lr], \quad T_5 = [1, 1, s]$ 

as class representatives under parastrophic equivalence.

Now let us consider the case when $\sigma \neq 1$, i.e. the type $[1, \sigma, \tau]$. As a consequence of condition (1.16), we also have:

$$(1.17) \quad \sigma \neq 1, \quad \tau \neq 1, \quad \sigma \neq \tau.$$ 

Indeed, suppose that $\tau = 1$, $T = [1, \sigma, 1]$. But then $f^2T = [1, 1, \sigma]$, so $T \sim T_i$, where $i$ is one of the numbers 2, 3, 4, 5. If $\sigma = \tau$, then $T = [1, \sigma, \sigma]$, whence $fT = [\sigma, \sigma, 1] = [1, 1, \sigma^{-1}]\sigma$ and therefore $T = f^2[1, 1, \sigma^{-1}]\sigma$ so $T \sim [1, 1, \sigma^{-1}]$. That is, $T \sim T_6$. Taking into account conditions (1.16) and (1.17), the following representatives for the equivalence classes are possible:

$T_6 = [1, l, br], \quad T_7 = [1, l, s], \quad T_8 = [1, rl, br],$

$T_9 = [1, rl, s], \quad T_{10} = [1, lr, l], \quad T_{11} = [1, lr, rl],$

$T_{12} = [1, s, l], \quad T_{13} = [1, s, rl].$

We shall show that

$T_{13} \sim T_{10} \sim T_7,$

$T_{12} \sim T_9 \sim T_6.$

Indeed, we have

$hT_{10} = h[1, lr, l] = [rf, rlr, r] = [1, lrllr, s]rl = [1, l, s]rl = T_7rl,$

$fT_{13} = f[1, s, rl] = [s, rl, 1] = [1, rls, s]s = [1, rllrl, s]s = [1, l, s]s = T_7s.$
Consequently, $T_{10} \sim T_{7}$ and $T_{13} \sim T_{7}$.

Furthermore, we have

\begin{align*}
  fT_9 &= f[1, rl, s] = [rl, s, 1] = [1, slr, lr]rl = [1, l, lr]rl = T_6rl, \\
  fT_{12} &= f[1, s, l] = [s, l, 1] = [1, ls, s]s = [1, rl, s] = T_9s.
\end{align*}

Therefore, $T_9 \sim T_6$ and $T_{12} \sim T_9$.

We have also the equivalences:

\begin{align*}
  T_5 &\sim T_2, \\
  T_4 &\sim T_3. 
\end{align*}

Indeed,

\begin{align*}
  fhT_5 &= fh[1, 1, s] = f[r, r, rs] = [1, 1, rs]r = [1, 1, l]r = T_2r, \\
  fhT_4 &= fh[1, 1, lr] = f[rlr, r, r] = [r, r, s]rs = [1, 1, sr]r = [1, 1, rl]r = T_3r.
\end{align*}

We shall use the second equality again later, so we write

\begin{equation}
  fhT_4 = T_3r. 
\end{equation}

This proves the equivalences (1.18), so finally only the following class representatives for parastrophic equivalence remain:

\begin{align*}
  T_1, T_2, T_4, T_6, T_8, T_{10}, T_{11}. 
\end{align*}

We shall show that the seven types listed in (1.20) are pairwise parastrophically non-equivalent.

a) $T_8$ and $T_{11}$ are parastrophically non-equivalent to any other type. This follows from the following relations:

\begin{align*}
  fT_8 &= T_8rl, \\
  f^2T_8 &= T_8lr, \\
  hT_8 &= T_8s, \\
  fhT_8 &= T_8l, \\
  f^2hT_8 &= T_8r, \\
  fT_{11} &= T_{11}lr, \\
  f^2T_{11} &= T_{11}rl, \\
  hT_{11} &= T_{11}l, \\
  fhT_{11} &= T_{11}s, \\
  f^2hT_{11} &= T_{11}r. 
\end{align*}

Thus, any type $T' \neq T_8$ which is parastrophically equivalent to $T_8$ has the form $gT_8\alpha = (T_83)\alpha = T_8\gamma = \gamma, \varphi, \psi$, where $\gamma \neq 1$, i.e. none of the types (1.20) is equivalent to $T_8$ other than $T_8$ itself. An analogous assertion is valid for $T_{11}$.

b) We shall use the following trivial observations. If all the components of $T$ are identical and $T' \sim T$, then all the components of $T'$ also are identical.
If two components of $T$ are identical and $T' \sim T$, then two components of $T'$ also are identical.

From this it follows at once that none of the types (1.20) is parastrophically equivalent to $T_1$ (except $T_1$ itself).

c) From a) and b) it follows that $T_6$ and $T_7$ and, likewise, $T_2$ and $T_4$, are parastrophically non-equivalent pairs.

The types $T_6$ and $T_7$ cannot be parastrophically equivalent to $T_2$ and $T_4$ because $T_2$ and $T_4$ have two identical components, while $T_6$ and $T_7$ have their components all different.

We shall show that $T_2 \not\sim T_4$. For this purpose, we determine $gT_2$, where $g$ runs through the whole group $S^6$:

$$gT_2 = [1, 1, l], [1, l, 1], [l, 1, 1], [rl, r, r], [r, r, rl].$$ (1.22)

Now we determine $T_4\alpha$, where $\alpha$ runs through the whole group $S_3$:

$$T_4\alpha = [1, 1, lr], [r, r, l], [l, l, s], [rl, rl, 1], [lr, lr, rl], [s, s, r].$$ (1.23)

From (1.22) and (1.23), we conclude that $T_2 \not\sim T_4$. Similarly, we can prove that $T_6 \not\sim T_{10}$.

Therefore, we have seven classes for parastrophic equivalence, the representatives of which are listed in (1.20). We determine the identity defined by each of these types and, in each case, we obtain the equivalent identity when this identity is written in terms of the basic quasigroup operation $A$ alone.

1) Type $T_1 = [1, 1, 1]$. The corresponding identity is determined by the equality $AAA = E$. If $A = ( \cdot )$, then it is the following identity

$$x(x \cdot xy) = y.$$

2) Type $T_2 = [1, 1, l]$. The corresponding identity is determined by the equality $AA^lA = E$. If $A = ( \cdot )$, then $^lA = ( / )$ and the identity takes the form

$$x(x(x/y)) = y.$$ (1.24)

Let $x/y = z$, whence $x = zy$. Consequently (1.24) can be transformed into the following identity:

$$(zy)(zy \cdot z) = y.$$

Multiplying on the left by $z$ and replacing $zy$ by $x$, we obtain

$$z[(zy)(zy \cdot z)] = zy,$$ (1.25)
Thus, an identity of type $T_2$ is equivalent to (1.25).

3) Type $T_4 = [1, 1, lr]$. The corresponding identity is determined by the equality $AA^{lr}A = E$. Let $A = (\cdot)$, then $^{lr}A(x, y) = y/x$. Consequently, the identity has the form

$$x(x(y/x)) = y.$$  \hfill (1.26)

Let $y/x = z$, then $y = zx$. So the identity (1.26) can be transformed into the equality $x \cdot xz = zx$. This is Stein’s identity (or, in the terminology of [4], Stein’s first law).

4) Type $T_6 = [1, l, lr]$. To this type corresponds the equality $A^{lr}A^{l}A = E$. If $A = (\cdot)$, then $^{l}A = (\slash)$, $^{lr}A(x, y) = y/x$, and consequently $T_6$ determines the identity

$$x(x/(y/x)) = y.$$  \hfill (1.27)

Let $y/x = u$, $x/u = v$. Then $y = ux$, $x = vu$, whence $y = u \cdot vu$. The identity (1.27) becomes transformed into the form

$$vu \cdot v = u \cdot vu.$$

5) Type $T_{10} = [1, lr, l]$. We consider a type parastrophically equivalent to $T_{10'}$; namely, $fT_{10'} = [lr, l, 1]$. To this type corresponds the equality $^{lr}A^{l}AA = E$. If $A = (\cdot)$, then $^{l}A = (\slash)$, $^{lr}A(x, y) = y/x$ and the corresponding identity has the form:

$$(x/xy)/x = y,$$

whence it follows that $yx = x/xy$ and so

$$yx \cdot xy = x.$$

This is precisely Stein’s third law (see [4]).

6) Type $T_8 = [1, rl, lr]$. The corresponding identity is determined by the equality $A^{rl}^{lr}A = E$. If $A = (\cdot)$, then $^{rl}A(x, y) = y/x$, $^{lr}A(x, y) = y\backslash x$. Consequently, to the type $T_8$ corresponds the identity:

$$x((y/x)\backslash x) = y.$$  \hfill (1.28)

Let $y/x = u$, $u\backslash x = v$. Then $y = ux$, $x = uv$, whence $y = u \cdot uv$, and the identity (1.28) has the form

$$uv \cdot v = u \cdot uv.$$
In the terminology of [4], this is Schröder’s first law. Finally, we consider

7) Type $T_{11} = [1, lr, rl]$. The corresponding equality is $A^t A^r A = E$, and the corresponding identity has the form

$$x((y \setminus x)/x) = y.$$  (1.29)

Let $y \setminus x = u$, $u/x = v$. Then $x = yu$, $u = vx$. Consequently, the identity (1.29) takes the form $xv = y$. Combining the last equality with the others, we get

$$x = yu = xv \cdot vx,$$

i.e. (1.29) is equivalent to the identity

$$xv \cdot vx = x,$$

which is Schröder’s second law (see [4]).

We summarize the results obtained in the following table:

<table>

</table>

Table 1.

Thus, we have proved

**Theorem 1.** Any minimal nontrivial identity in a quasigroup is parastrophically equivalent to one of the identity types listed in (1.20). □

$^7$Editors’ Remark: Stein’s 2nd law is misquoted in [4] because of a compositing error.
Editors Comments: The same result\(^8\) was obtained later (1989) by F. E. Bennett \([10]\) working independently and using an earlier closely-related theorem due to T. Evans \([13]\). Bennett also investigated the spectrum of orders for which a quasigroup satisfying each particular one of the seven identity types exists. The results obtained by Bennett, Evans and other authors are summarized in Chapter 4, Section 36 of \([12]\). However, Belousov’s work on this topic and on Quasigroups in general is not mentioned in that summary. It is also the case that Belousov seemed unaware of the work of Evans which is closely related to his own and predates it. In fact, in the 1970s and 1980s, Congressus Numerantium was not available in USSR and Belousov’s published booklet was not available in Canada.

Example. Consider the minimal nontrivial identity

\[
\frac{x}{y} \cdot \frac{y}{x} = x,
\]  

or in alternative notation

\[
A^{-1}(-1A(x, y), A^{-1}(y, x)) = x.
\]

We transform the identity (1.31) to the form \(ABC = E\). We have

\[
A^{-1}(-1A(x, y), (A^{-1})^*(x, y)) = x,
\]

whence

\[
-1(A^{-1})(x, (A^{-1})^*(x, y)) = -1A(x, y).
\]

Let \(-1A(x, y) = z\). Then \(y = (-1A)^{-1}(x, z)\). Consequently, from (1.32) we obtain

\[
-1(A^{-1})(x, (A^{-1})^*(x, (-1A)^{-1}(x, z))) = z,
\]

or

\[
_{lr}A(x, _{sr}A(x, _{rl}A(x, z))) = z,
\]

\[
_{lr}A_{sr}A_{rl}A = E,
\]

i.e. Our identity has type \(T = [lr, sr, rl] = [lr, rl, rl]\). We transform \(T\):

\[
T = [lr, rl, rl] = [lrlr, 1, 1]rl = [rl, 1, 1]rl
\]

\[
= f^2[1, 1, rl]rl = f^2T_3rl.
\]

\(^8\)Bennett’s list consists of \(T_4, T_8, T_{10}, T_{11}\) and the duals of \(T_1, T_6\) and \(T_5\) (equivalent to \(T_2\)).
But, \( T_3 = fhT_4r \) (as was proved in \((1.19)\)), whence

\[
T = f^2(fhT_4r)rl = hT_4l.
\]

Consequently, \( T \) is parastrophically equivalent to \( T_4 \), and the identity \((1.30)\) is equivalent to an identity of type \( T_4 \), i.e. to Stein’s identity for \( I_A = (/). \)

Indeed, let \( (\circ) = (/) \), so that \( x/y = x \circ y \). From \((1.30)\), it follows that

\[
(x \circ y)(y \backslash x) = x,
\]

\[
(x \circ y)x = y \backslash x,
\]

\[
y((x \circ y)x) = x. \quad (1.33)
\]

Let \( (x \circ y)x = z \). Then \( x \circ y = z/ = z \circ x \) and from \((1.33)\) we obtain

\[
x/((x \circ y)x) = y, \quad x \circ ((x \circ y)x) = y.
\]

Finally, \( x \circ y = z \circ x \) and \( x \circ z = y \) imply the Stein law \( x \circ (x \circ z) = z \circ x \).

**Remarks.**

1) The names of the identities (in Table 1) originate from Sade’s paper \([7]\). In this paper a list of 63 identities, basic identities and generalized identities, is given. The identities of types \( T_4, T_6, T_8, T_{10}, T_{11} \) are given the numbers 12, 13, 14, 16, 15 respectively in \([7]\) and these names are cited in the monograph of Dénes and Keedwell \([4]\).

2) In Norton and Stein’s paper \([5]\), idempotent quasigroups satisfying the identity \( T_{11} \) \((xy \cdot yx = x) \) are considered. These authors obtained a condition on the order which holds for a quasigroup of this type and also one for the finite idempotent quasigroups which satisfy the identity \( T_{10} \) \((xy \cdot yx = y) \). Furthermore, they gave examples of such quasigroups: namely, the ones which are defined by the following tables:

\[
\begin{array}{cccc}
  a & b & c & d \\
  a & a & c & d \\
  b & d & b & a \\
  c & b & d & c \\
  d & c & a & b \\
\end{array}
\]

Table 2.

\[
\begin{array}{cccc}
  a & b & c & d & e \\
  a & a & c & d & e \\
  b & b & d & e & c \\
  c & e & a & c & b \\
  d & b & e & a & d \\
  e & c & d & b & a \\
\end{array}
\]

Table 3.

3) Quasigroups satisfying the identity \( T_4 \) \((x \cdot xy = yx) \) are considered in the paper \([8]\) by Stein. The following example is given of a Stein quasigroup (i.e. of a quasigroup satisfying Stein’s first law \( T_4 \)). The epithet "Stein quasigroup" was given in \([3]\) for brevity.
As can be seen, the quasigroups given in Table 2 and Table 4 are identical, i.e. they satisfy both of the identities $T_4$ and $T_{11}$: $x \cdot xy = yx$, $xy \cdot yx = x$. They also satisfy the identity $xy \cdot x = y$, called the identity of semisymmetry in Sade’s terminology [7], who devoted a series of papers to them.

4) In Stein’s paper [8] the identities $T_6$ ($xy \cdot x = y \cdot xy$) and $T_8$ ($xy \cdot y = x \cdot xy$) are mentioned and examples of such quasigroups are constructed.

5) Minimal identities occur in the study of paratopy of OSQ (see §0). Let $\Sigma = \{A_i\}$, $i = 1, 2, \ldots, k$, be an OSQ. A permutation $\bar{\theta}$ of the set $Q^2$ is called a paratopy of the OSQ $\Sigma$ if the system $\{A_1\bar{\theta}, A_2\bar{\theta}, \ldots, A_k\bar{\theta}\}$ is identical to $\Sigma$. For $k = 4$ (for $k \leq 3$ we have trivial cases) an OSQ admitting at least one paratopy can be one of nine types [2]. These systems take the form $\{F, E, A, A'\}$, where $A'$ can be expressed in terms of $A$. For example, $A' = A^*$, $A' = (-1)^{-1}A$, and so on. In seven of these cases it has been shown that the quasigroup must satisfy some minimal identity. Two of these identities are $T_1$ and $T_{10}$, while the other five are parastrophically equivalent to identities of type $T_1$, $T_{10}$ and $T_6$.

Orthogonality and parastrophy.

In the preceding Section, we showed that, if $Q(\cdot)$ is a $\Pi$-quasigroup, $(\cdot) = A$, of type $[\alpha, \beta, \gamma]$, then the following parastrophes are pairwise orthogonal

$$\alpha \perp r\beta, \quad \beta \perp r\gamma, \quad \gamma \perp r\alpha.$$  \hspace{1cm} (1.34)

In order to describe all mutually orthogonal parastrophes of a quasigroup of one of the seven types mentioned above, we first look at some properties of orthogonality of parastrophes. We recall that $\alpha \perp \beta(\sigma)$ means that $\alpha \perp \beta(\sigma)$.

1) If $\alpha \perp \beta$, then $s\alpha \perp s\beta$. Indeed, this follows from the more common assertion: If $A \perp B$, then $A^* \perp B^*$ and conversely. The latter statement follows from the fact that the system of equations $A(x, y) = a$, $B(x, y) = b$ is equivalent to the system of equations $A^*(y, x) = a$, $B^*(y, x) = b$.

<td>c</td>
<td>a</td>
<td>b</td>
<td>d</td>
</tr>
</tbody>
</table>

Table 4.
2) If $\alpha \perp \beta$, then $1 \perp \beta \alpha^{-1}(\alpha)$, $1 \perp \alpha \beta^{-1}(\beta)$. This follows from the fact proved above: $\alpha \perp \beta(\sigma)$ is equivalent to $a \sigma \perp \beta(\sigma)$.

We return to the discussion of orthogonality of parastrophes of $\Pi$-quasigroups. By property 1), the following orthogonalities follow from (1.34):

$$sa \perp sr\beta, \ s\beta \perp sr\gamma, \ s\gamma \perp sr\alpha,$$

or

$$sa \perp rl\beta, \ s\beta \perp rl\gamma, \ s\gamma \perp r\alpha.$$  

Applying property 2) for $T = [\alpha, \beta, \gamma]$ to the orthogonalities (1.34) and (1.35), we obtain

$\begin{align*}
1 \perp r\beta\alpha^{-1}(\alpha), & \quad 1 \perp r\gamma\beta^{-1}(\beta), & \quad 1 \perp r\alpha\gamma^{-1}(\gamma), \\
1 \perp \alpha\beta^{-1}r(\beta), & \quad 1 \perp \beta\gamma^{-1}r(\gamma), & \quad 1 \perp \gamma\alpha^{-1}r(\alpha), \\
1 \perp rl\beta\alpha^{-1}s(\alpha), & \quad 1 \perp rl\gamma\beta^{-1}s(\beta), & \quad 1 \perp rl\alpha\gamma^{-1}s(\gamma), \\
1 \perp sa\beta^{-1}lr(rl\beta), & \quad 1 \perp s\beta\gamma^{-1}lr(rl\gamma), & \quad 1 \perp s\gamma\alpha^{-1}lr(rl\alpha).
\end{align*}$

In particular, for the case $\alpha = 1$, we get

$\begin{align*}
1 \perp r\beta(1), & \quad 1 \perp r\gamma\beta^{-1}(\beta), & \quad 1 \perp r\gamma^{-1}(\gamma), \\
1 \perp \beta^{-1}r(\beta), & \quad 1 \perp \beta\gamma^{-1}r(\gamma), & \quad 1 \perp \gamma r(\beta), \\
1 \perp rl\beta s(s), & \quad 1 \perp rl\gamma\beta^{-1}s(\beta), & \quad 1 \perp rl\gamma^{-1}s(\beta), \\
1 \perp s\beta^{-1}lr(rl\beta), & \quad 1 \perp s\beta\gamma^{-1}lr(rl\gamma), & \quad 1 \perp s\gamma lr(rl). 
\end{align*}$

Applying the relations (1.37) to $\Pi$-quasigroups of the types given in Table 1, we obtain the results presented below.

<table>
<thead>

</table>

Table 5.
Here, for the sake of brevity, we have written $\alpha \perp \theta(\beta_1, \beta_2, \ldots, \beta_k)$ instead of $\alpha \perp \theta(\beta_1), \alpha \perp \theta(\beta_2), \ldots, \alpha \perp \theta(\beta_k)$. If we restrict ourselves to parastrophes of the basic operation, i.e. to orthogonalities of the form $\alpha \perp \beta$, then (taking into account the equivalence $\alpha \perp \beta(\theta) \leftrightarrow \alpha \perp \beta(\theta)$), we obtain the following table:

<table>

Table 6.

We end this Section with some remarks.

**Remark 1.** Identities of type $T_8$ and $T_{11}$ are invariant under parastrophy, i.e. these identities hold in any parastrophe. Indeed, from (1.21) it follows that, for an arbitrary parastrophe $\sigma$, there exists a transformation $g \in S^0$, such that $gT_8 = T_8\sigma$. From the remark after Definition 2 it follows that, if the identity $T_8$ holds in $Q(A)$, then the identity $gT_8\sigma^{-1}$ holds in $Q(\sigma^A)$: that is, by virtue of (1.21), $T_8$ holds in $Q(\sigma^A)$ for every $\sigma \in S_3$. The same assertion holds for an identity of type $T_{11}$.

These facts can be proved directly. Consider an identity of type $T_{11}$. That is, one which is equivalent to

$$xy \cdot yx = x. \quad (1.38)$$

Let $xy = u, yx = v$, then $uv = x$. From these equalities it follows that $x \setminus u = y, y \setminus v = x, u \setminus x = v$. Hence $x = y \setminus v = (x \setminus u)(u \setminus x)$, that is, $(x \setminus u)(u \setminus x) = x$. From the same relations $xy = u, yx = v, uv = x$ it follows

---

9 In a paper of M. E. Stickel and H. Zhang[15], these authors claimed incorrectly that the following results from Belousov’s Table 5 were new: For a quasigroup of type $T_{10}$, $1 \perp rl(l, rl)$ (re-proved by Stickel, 1994) and, for a quasigroup of type $T_8$, $1 \perp l(r, lr)$ (stated in the paper just mentioned). (In the notation of Stickel and Zhang, “a parastrophe of $QG_4$ satisfies $QG_2$ and a parastrophe of $QG_7$ satisfies $QG_1$.”)

10 Table 3 of Stickel and Zhang’s 1994 paper[15] (which was obtained with the aid of a computer) contains the same information as Belousov’s Table 6 below.
at once that $u/y = x$, $v/x = y$, $x/v = u$, whence $x = u/y = (x/v)/(v/x)$, i.e.

$$(x/v)/(v/x) = x. \quad (1.39)$$

So the identity $T_{11}$ holds both in $Q(\mathfrak{f})$ and in $Q(\mathfrak{\setminus})$, and hence it holds in
the other parastrophes too.

Furthermore, it follows from the above that the identities (1.38) and (1.39) are not only parastrophically equivalent but they are equivalent in
the usual sense as well.

**Remark 2.** 1) Quasigroups satisfying any one of the identities $T_4$, $T_{10}$, $T_{11}$ are anti-commutative (that is, the equality $ab = ba$ holds if and only if $a = b$).

We begin with the identity $T_{10}$. Let $ab = ba = c$. Then $c^2 = ab \cdot ba = b$ and $c^2 = ba \cdot ab = a$. Consequently, $a = b$. Similarly, we can show this fact
for $T_{11}$.

In the case of $T_4$ we have $ac = a \cdot ab = ba = c$, $bc = b \cdot ba = ab = c$, i.e. $ac = bc$, whence $a = b$.

2) Quasigroups satisfying any one of the identities $T_3$, $T_6$, $T_8$ are idempotent. Indeed, for Stein’s law ($T_4$) idempotency follows directly by putting
$x = y$. This gives $x \cdot x^2 = x^2 = xx$, whence $x^2 = x$. In the identity $T_6$
($xy \cdot x = y \cdot xy$), let $y = e_x$, where $xe_x = x$.11 Then $xe_x \cdot x = e_x \cdot xe_x$ or
$xx = xe_x$: that is, $x = e_x$. Then $x^2 = xx = xe_x = x$. Finally, putting
$y = e_x$ in $T_8$ ($xy \cdot y = x \cdot xy$), we obtain $x = x^2$.

§2. Π-quasigroups.

Π-quasigroups are defined by identities containing only two free variables
so we should not expect to obtain their complete description: that is, the
description of all loops which are isotopic to these quasigroups.

First, the following question arises: “For which values of $n$ (where $n$
is a natural number) do there exist Π-quasigroups of type $[\alpha, \beta, \gamma]$?”
This question is combinatorial in character and several investigations concerning
it have been made: for example, the papers of Phelps who considered
orthogonality of the form $A \perp \sigma A$, where $\sigma A$ is a parastrophe of $A$. Such an
orthogonality is connected with the equality $A' A \perp \sigma A = E$ or $A' A \perp \sigma A = E$
(i.e. $A$ and $\tau$ determine $A'$). Therefore, it leads to a class of quasigroups

---

11Editors’ Note: The element $e_x$, so defined, is called the right local identity for the
element $x$. 
more general than the class of II-quasigroups. In [6] the spectrum\textsuperscript{12} of $A$
 is considered, i.e. the collection of all positive integers $n$ for which there
exists $A \perp n$.

Here we consider a different question. It is known [3] that if a Stein
quasigroup (in our classification a II-quasigroup of type $T_4$) is isotopic to a
group, then that group is metabelian. We are interested in analogous ques-
tions for other II-quasigroups: that is, we shall investigate II-quasigroups
isotopic to groups. We shall consider each type separately.

1) II-quasigroups $A = (\cdot)$ of type $T_1 = [1, 1, 1]$.

In such a quasigroup, the following identity is satisfied:

$$x(x \cdot xy) = y.$$  \hspace{1cm} (2.1)

Let $x + y = R_a^{-1}x \cdot L_b^{-1}y$, so that $Q(\cdot)$ is a loop with $0 = ba$ as identity
element. For the sake of brevity, let $R_a = R$, $L_b = L$. Then $xy = Rx + Ly$,
and replacing the operation $(\cdot)$ by $(\cdot)$ in (2.1), we get

$$Rx + L(Rx + L(Rx + Ly)) = y,$$

or

$$x + L(x + L(x + Ly)) = y.$$ \hspace{1cm} (2.2)

By putting $x = 0$, we deduce that $L^3 = 1$\textsuperscript{13}.

From (2.2) we deduce that

$$x + L(x + Ly) = L^{-1}(-x + y),$$

whence

$$x + L(x + y) = L^{-1}(-x + L^{-1}y).$$ \hspace{1cm} (2.3)

For a suitable choice of $a, b$ we can make $L^{-1}0 = 0$. Indeed, $L^{-1}0 = 0$
is equivalent to $L0 = 0$ or $L_a(ba) = ba$, $b \cdot ba = ba$, whence $ba = a$, i.e. it is
necessary that $b = f_a$, where $f_a$ is the left local identity for the element $a$
(cf. the right local identity $e_a$ used earlier). Putting $y = 0$ in (2.3) we have

$$x + Lx = L^{-1}(-x).$$ \hspace{1cm} (2.4)

\textsuperscript{12}Editors’ Note: A lot of work has been done on this question in recent years. The
interested reader will find a summary of the results obtained prior to 1996 in [12] which
we mentioned earlier. A more recent paper on this topic is [11] by F.E. Bennett and H.
Zhang.

\textsuperscript{13}The original text says "If $x = 0$, then $L^3 = 1"."
With the help of (2.4) we can transform (2.3):

\[ L^{-1}(-x + L^{-1}y) = L^{-1}(-x + L^{-1}(-(-y))) = L^{-1}(-x - y + L(-y)) = -(-x - y + L(-y) + L(-(-x - y + L(-y)))) = -L(-y) + y + x + L(-L(-y) + y + x). \]

Thence, after replacing \(-y\) by \(y\) and using (2.3), we get

\[ -Ly - y + x + L(-Ly - y + x) = x + L(x - y). \]  \hfill (2.5)

Let \(-Ly - y + x = u\) so that \(x = y + Ly + u\). Then the equality (2.5) takes the form

\[ u + Lu = y + Ly + u + L(y + Ly + u - y), \]

whence

\[ L(y + Ly + u - y) = -u - Ly - y + u + Lu. \]  \hfill (2.6)

Now (2.4) and (2.6) together imply that

\[ L(L^{-1}(-y) + u - y) = -u - L^{-1}(-y) + L^{-1}(-u). \]

Writing \(-v\) for \(y\) and \(-u\) for \(u\), we have

\[ L(L^{-1}v - u + v) = u - L^{-1}v + L^{-1}u, \]

whence

\[ L^{-1}(u - L^{-1}v + L^{-1}u) = L^{-1}v - u + v. \]

Let \(L^{-1} = \lambda\). Then

\[ \lambda(u - \lambda v + \lambda u) = \lambda v - u + v. \]  \hfill (2.7)

We introduce a new operation:

\[ v \circ \lambda u = \lambda v - u + v. \]

---

**Editors’ Note:** provided that \(b = f_a\) and that (+) is an associative operation.

Belousov states at the beginning of this Section that he is interested in quasigroups of each type \(T_i\) which are isotopic to groups. It follows that the loop principal isotope \((Q,+)\) of a quasigroup of type \(T_1\) is itself isotopic to a group and so, by Albert’s Theorem (Theorem 1.4 of [1] or Theorem 1.3.4 of [4]), this principal isotope is a group. The main results of this long subsection are that \((Q,+)\) satisfies the relation \(2x + 2y + 2z = 2(x + y + z)\) and that, if there is an element \(0\) in \(Q\) satisfying the relation (2.11), then there is a loop \((Q,+)\) defined as in (2.16), for which Theorems 2 and 3 hold. However, the loop \((Q,+)\) itself does not appear to be isotopic either to \((Q,+)\) or to the original quasigroup \((Q,\cdot)\) of type \(T_1\).
It is easy to see that $Q(\circ)$ is a quasigroup: using the equality (2.7), we find that the equations $a \circ x = b, y \circ a = b$ are equivalent to the equations:

$$\lambda a - x + a = b, \quad \lambda(a - \lambda y + \lambda a) = b$$

which are uniquely soluble for any given $a, b \in Q$. In what follows, we shall suppose that

$$\lambda I = I \lambda,$$

where $Ix = -x$. The relation $\lambda I = I \lambda$ is equivalent to $LI = IL$.

We should like to know under what conditions this last equality holds. First we remark that, because $0 = ba = f_a a = a$, we have

$$R^{-1}x = R_a^{-1}x = R_0^{-1}x = x/0$$

and

$$L^{-1}x = L_b^{-1}x = L_{f_a}^{-1}x = L_{f_0}^{-1}x = f_0 \setminus x.$$ 

Therefore, $x + y = R_a x \cdot L_b^{-1} y = (x/0) \cdot (f_0 \setminus y)$. In particular, $x + Ix = 0$ implies that $(x/0) \cdot (f_0 \setminus Ix) = 0$, whence we obtain

$$f_0 \setminus Ix = (x/0) \setminus 0.$$ 

We have $f_0 \setminus Ix = L^{-1}Ix$ from above. Let $\varphi x = L^{-1}Ix$, then

$$(x/0) \setminus 0 = \varphi x.$$ 

But $\varphi L = L \varphi$, because $\varphi = L^{-1}I$ and $LI = IL$. Thus, since

$$\varphi Lx = (Lx/0) \setminus 0$$

(by putting $Lx$ for $x$ in the preceding equation) and since

$$L\varphi x = L[(x/0) \setminus 0],$$

follows directly from the same preceding equation, we get

$$(Lx/0) \setminus 0 = L[(x/0) \setminus 0].$$

Since $L = L_b = L_{f_a} = L_{f_0}$, it follows that

$$(f_0x/0) \setminus 0 = f_0[(x/0) \setminus 0].$$

(2.8)

\textsuperscript{15}The following three lines of textual explanation were not in the original text or its translation.
Let
\[(x/0)\cdot 0 = u, \quad (f_0x/0)\cdot 0 = v. \quad (2.9)\]
Then (2.8) implies that
\[v = f_0u \quad (2.10)\]
and, from (2.9), we get
\[(x/0) \cdot u = 0, \quad (f_0x/0) \cdot v = 0, \quad (2.11)\]
whence it follows that
\[0/u = x/0, \quad 0/v = f_0x/0. \quad (2.11)\]
These equalities, together with (2.10), imply that
\[x = (0/u) \cdot 0, \quad f_0x = (0/v) \cdot 0 = (0/f_0u) \cdot 0. \quad (2.11)\]
So, finally we get
\[f_0[(0/u)0] = (0/f_0u)0. \quad (2.11)\]

We prove the converse statement: if there is an element 0 in Q satisfying the condition (2.11) then, in the isotope \(x + y = R_a^{-1}x \cdot L_b^{-1}y\), where \(a = 0\) and \(b = f_0\), the equality \(LI = IL\) is satisfied with \(L = L_{f_0}\) and \(R = R_0\).

First we note that \(0/u = I_0^{-1}u\), where the mapping \(I_0\) is determined by the equality \(x \cdot I_0x = 0\). Thus, (2.11) is equivalent to the equality \(L_{f_0}R_0I_0^{-1} = R_0I_0^{-1}L_{f_0}\) or
\[LRI_0^{-1} = RLI_0^{-1}. \quad (2.12)\]
In order to express \(I_0\) in terms of \(I\), we replace the operation (+) by (\cdot) in the equation \((x +Ix) = 0\) so as to get \(R_a^{-1}x \cdot L_b^{-1}Ix = 0\) or, for brevity, \(R^{-1}x \cdot L^{-1}Ix = 0\) and so \(x \cdot L^{-1}IRx = 0\), whence, by the definition of \(I_0\), we obtain \(I_0 = L^{-1}IR\). Substituting this expression into (2.12), we get \(LR(R^{-1}IL) = R(R^{-1}IL)\), whence it follows that \(LI = IL\).

Assume now that an element 0 satisfying (2.11) exists (so that \(LI = IL\) and \(\lambda L = L\lambda\)). Under this assumption it follows from (2.7) that
\[\lambda I(-\lambda u + \lambda v - u) = v \circ u, \quad \lambda I(I\lambda u + \lambda v + Iu) = v \circ u, \quad \lambda I(\lambda Iu - I\lambda v + Iu) = v \circ u, \quad (2.13)\]
\[ \lambda I(Iu \circ I\lambda v) = v \circ u, \quad (2.13) \]

or

\[ (\lambda I)^{-1}(v \circ u) = Iu \circ I\lambda v, \]

whence (using the preceding equality twice) it follows that

\[ (\lambda I)^{-2}(v \circ u) = (\lambda I)^{-1}(Iu \circ I\lambda v) = I^2 \lambda v \circ I\lambda Iu \]

and so

\[ (\lambda I)^{-2}(v \circ u) = \lambda v \circ \lambda u, \]

because \(I^2 = 1\) and \(\lambda I = I\lambda\). But \((\lambda I)^{-2} = \lambda^{-2}I^{-2} = \lambda^{-2} = L^2 = L^{-1}\) because \(L^3 = 1\). Thus,

\[ \lambda(v \circ u) = \lambda v \circ \lambda u, \]

i.e. \(\lambda\) is an automorphism of the quasigroup \(Q(\circ)\).

We determine a loop which is an \(LP\)-isotope of the quasigroup \((\circ)\) and for which the \(LP\)-isotopism is given by

\[ x \oplus y = \bar{R}_0^{-1}x \circ \bar{L}_0^{-1}y, \quad (2.14) \]

where \(\bar{R}_0x = x \circ 0\) and \(\bar{L}_0x = 0 \circ x\).

We remark that \(0 \circ 0 = 0\), i.e. \(0\) is the identity of the loop \(Q(\oplus)\). Indeed, \(0 \circ 0 = \lambda 0 - 0 + 0 = \lambda 0 = L_{f_0}^{-1}0 = 0\). Moreover, we have

\[ \bar{L}_0x = 0 \circ x = \lambda 0 - x + 0 = -x = Ix, \]

\[ \bar{R}_0x = x \circ 0 = \lambda x - 0 + x = \lambda x + x = L^{-1}x + x = L^{-1}x + L(L^{-1}x). \]

Taking into account the equality \((2.4)\), we obtain

\[ \bar{R}_0x = L^{-1}(-L^{-1}x) = L^{-1}IL^{-1}x = L^{-2}Ix = LIx. \]

So, \(\bar{L}_0^{-1} = I\), \(\bar{R}_0^{-1} = IL^{-1} = I\lambda\) and consequently

\[ x \oplus y = I\lambda x \circ Iy. \quad (2.15) \]

From this and the definition of the operation \((\circ)\), we conclude that

\[ x \oplus y = \lambda I\lambda x - Iy + I\lambda x, \quad \text{or} \quad x \oplus y = I\lambda^2x + y + I\lambda x. \]

But \(\lambda^2 = L^{-2} = L = \lambda^{-1}\), hence

\[ x \oplus y = I\lambda^{-1}x + y + I\lambda x. \quad (2.16) \]

We prove the following assertion.
**Theorem 2.** The loop $Q(\oplus)$ defined by the equality (2.14) is a Moufang
loop.

**Proof.** We show first that $\lambda$ is an automorphism of the loop $Q(\oplus)$. For this
purpose, we use the equality (2.15) and the fact that $\lambda$ is an automorphism
of $Q(\circ)$. We have

$$
\lambda(x \oplus y) = \lambda(I\lambda x \circ Iy) = \lambda I\lambda x \circ \lambda Iy = I\lambda(\lambda x) \circ I\lambda y = \lambda x \oplus \lambda y,
$$

so

$$
\lambda(x \oplus y) = \lambda x \oplus \lambda y. \quad (2.17)
$$

Next we show that $I$ is an anti-automorphism of the loop $Q(\oplus)$. For this
purpose, we replace the operation ($\circ$) in (2.13) by ($\oplus$) with the aid of (2.15):

$$
\lambda(I\lambda^{-1}Iu \oplus I^{-1}I\lambda v) = \lambda^{-1}I^{-1}v \oplus I^{-1}u,
$$

$$
I\lambda(\lambda^{-1}u \oplus \lambda v) = I\lambda^{-1}v \oplus Iu,
$$

$$
I(u \oplus \lambda^2v) = I\lambda^{-1}v \oplus Iu. \quad (2.18)
$$

Since $\lambda^2 = \lambda^{-1}$, by replacing $\lambda^{-1}v$ by $v$ in (2.18), we get

$$
I(u \oplus v) = Iv \oplus Ivu \quad (2.19)
$$

as required. We need also the following equality:

$$
\lambda x + x = x + \lambda x = \lambda^{-1}Ix \quad (2.20)
$$

which we now prove. Putting $u = 0$ and $v = 0$ in turn in the equality
(2.7), we get

1) putting $u = 0$: \( \lambda(-\lambda v) = \lambda v + v \) or

\( \lambda I\lambda v = \lambda v + v, \ \lambda^2 I v = \lambda v + v, \ \lambda^{-1}I v = \lambda v + v; \)

2) putting $v = 0$: \( \lambda(u + \lambda u) = -u \) or

\( u + \lambda u = \lambda^{-1}(-u), \ \ u + \lambda u = \lambda^{-1}Iu. \)

Finally, we prove the relation:

$$
(x \oplus y) \oplus x = x + y + x. \quad (2.21)
$$

Using (2.19) and then (2.16) twice, we have

$$
(x \oplus y) \oplus x = I(Ix \oplus I(x \oplus y)) = I(I\lambda^{-1}Ix + I(x \oplus y) + I\lambda Ix)
$$

$$
= I^2\lambda Ix + I^2(x \oplus y) + I^2\lambda^{-1}Ix = \lambda Ix + (x \oplus y) + \lambda^{-1}Ix
$$

$$
= \lambda Ix + \lambda^{-1}Ix + y + \lambda Ix + \lambda^{-1}Ix.
$$
But, from (2.20), \( \lambda Ix + \lambda^{-1}Ix = \lambda Ix + \lambda^2Ix = \lambda Ix + \lambda(\lambda Ix) = \lambda^{-1}I(\lambda Ix) = \lambda^{-1}II\lambda x = x \). Consequently, \((x \oplus y) \oplus z = x + y + x\).

Now it is easy to show that \(Q(\oplus)\) is a (left) Bol loop. We calculate separately the left and right hand sides of the Bol identity:

\[
w_1 = x \oplus (y \oplus (x \oplus z)) = I\lambda^{-1}x + (I\lambda^{-1}y + (I\lambda^{-1}x + z + I\lambda x) + I\lambda y) + I\lambda x,
\]
\[
w_2 = (x \oplus (y \oplus x)) \oplus z = I\lambda^{-1}(x \oplus (y \oplus x)) + z + I\lambda(x \oplus (y \oplus x))
\]

from (2.16). But, by (2.17), (2.19) and (2.21), we have

\[
I\lambda(x \oplus (y \oplus x)) = I(\lambda x \oplus \lambda(y \oplus x)) = I\lambda(y \oplus x) \oplus I\lambda x = (I\lambda x \oplus I\lambda y) \oplus I\lambda x = I\lambda x + I\lambda y + I\lambda x.
\]

Similarly, we obtain

\[
I\lambda^{-1}(x \oplus (y \oplus x)) = I\lambda^{-1}x + I\lambda^{-1}y + I\lambda^{-1}x.
\]

Therefore we get the following expression for \(w_2\):

\[
w_2 = (I\lambda^{-1}x + I\lambda^{-1}y + I\lambda^{-1}x) + z + (I\lambda x + I\lambda y + I\lambda x).
\]

Comparing the forms of \(w_1\) and \(w_2\) thus obtained and using the fact that (+) is an associative operation, we conclude that \(w_1 = w_2\); that is, we obtain the Bol identity. In order to show that \(Q(\oplus)\) is in fact a Moufang loop it is sufficient to apply the anti-automorphism \(I\) to both sides of the left Bol identity \(w_1 = w_2\), where \(w_1\) and \(w_2\) are determined as above, and then after replacing \(Ix, Iy\) and \(Iz\) by \(x, y\) and \(z\) respectively, we obtain the right Bol identity. But if \(Q(\oplus)\) is both a left and right Bol loop, then it is a Moufang loop [1]. Our theorem is proved.

The following result also is true.

**Theorem 3.** The loop \(Q(\oplus)\) is a group if and only if \(Q(+)=a\) metabelian group.

**Proof.** Indeed, from (2.16), we have

\[
x \oplus (y \oplus z) = I\lambda^{-1}x + (I\lambda^{-1}y + z + I\lambda y) + I\lambda x,
\]
\[
(x \oplus y) \oplus z = I\lambda^{-1}(x \oplus y) + z + I\lambda(x \oplus y).
\]
Equating the right hand sides of these equations, assuming that \((Q, \oplus)\) is a group, and then transferring terms,\(^{16}\) we obtain
\[
[l^{-1}(x \oplus y) + l^{-1}x + l^{-1}y] + z = z + [l(x \oplus y) + lx + ly]. \tag{2.22}
\]
Putting \(z = 0\), we see that \(t_1 = t_2\), where
\[
t_1 = l^{-1}(x \oplus y) + l^{-1}x + l^{-1}y, \quad t_2 = l(x \oplus y) + lx + ly
\]
and it follows from (2.22) that \(t_1 = t_2\) is in the centre \(Z\) of the group \(Q(+)\). But
\[
t_1 = (\lambda^{-1}x \oplus \lambda^{-1}y) + l^{-1}x + l^{-1}y
\]
so the latter expression is an element of \(Z\). Replacing \(x, y\) by \(\lambda x, \lambda y\) respectively, we obtain
\[
(x \oplus y) + lx + ly \in Z,
\]
\[
l^{-1}x + y + lx + lx + ly \in Z,
\]
\[
l^{-1}x + y + (lx + \lambda x) + ly \in Z.
\]
But (2.20) implies \(x + \lambda x = l^{-1}lx = l^{-1}x\) and so
\[
l^{-1}x + y + l^{-1}x + ly \in Z,
\]
\[
-l^{-1}x + y + l^{-1}x - y \in Z.
\]
Replacing \(x\) by \(\lambda x\) and \(y\) by \(-y\), we get
\[
-x - y + x + y \in Z, \tag{2.23}
\]
i.e. \([x, y] \in Z\), where \([x, y]\) is the commutator of \(x, y\) in \(Q(+)\). The last relation shows that \(Q(+)\) is a metabelian group.

Conversely, starting from (2.23) and reversing the steps, we show that \(t_1 \in Z\). If we then show that \(t_1 = t_2\), it will follow that (2.22) holds. But this equality is equivalent to the associative law in \(Q(\oplus)\). We proceed to prove that \(t_1 = t_2\):
\[
t_1 = l^{-1}(x \oplus y) + l^{-1}x + l^{-1}y
\]
\[
= -((x \oplus y) + (x \oplus y)) + l^{-1}x + l^{-1}y \quad \text{by (2.20)}^{17}
\]
\[
= -\lambda(x \oplus y) - (x \oplus y) + l^{-1}x + l^{-1}y
\]
\[
= l\lambda(x \oplus y) - (l^{-1}x + y + l\lambda x) + l^{-1}x + l^{-1}y \quad \text{by (2.16)}^{17}
\]
\[
= l\lambda(x \oplus y) - lx + y - l^{-1}x + l^{-1}x + l^{-1}y
\]
\[
= l\lambda(x \oplus y) + lx - y + l^{-1}y = l\lambda(x \oplus y) + lx - y + y + ly \quad \text{by (2.20)}^{17}
\]
\[^{16}\text{Editors' Note: We add } l^{-1}(x \oplus y) \text{ on the left to both sides, then } \lambda x \text{ on the right and finally } \lambda y \text{ on the right.}\]
\[ V. \text{ D. Belousov} \]

\[ = I\lambda(x \oplus y) + \lambda x + \lambda y = t_2. \]

Thus, \( t_1 = t_2 \) and the theorem is proved. \( \square \)

Finally, we show that a group \( Q(+) \) which is isotopic to a \( \Pi \)-quasigroup satisfying the identity \( T_1 \) must satisfy the identity

\[ 2(x + y + x) = 2x + 2y + 2x. \quad (2.24) \]

Indeed, consider the loop \( Q(\oplus) \). In this loop we have the equality

\[ I(x \oplus y) = Iy \oplus Ix. \]

Replacing \( (\oplus) \) by \( (+) \) in this identity and using (2.16), we obtain

\[ I(I\lambda^{-1}x + y + I\lambda x) = I\lambda^{-1}(Iy) + Ix + I\lambda(Iy). \]

\( L.H.S. = -(-\lambda^{-1}x + y - \lambda x) = \lambda x - y + \lambda^{-1}x \) so we get

\[ \lambda x + Iy + \lambda^{-1}x = \lambda^{-1}y + Ix + \lambda y. \quad (2.25) \]

Since \( \lambda^{-1}x = -I\lambda^{-1}x = -(x + \lambda x) = -(\lambda x + x) \) by (2.20), we have \( \lambda^{-1}x = -\lambda x - x \) and \( \lambda^{-1}y = -y - \lambda y \) and so (2.25) implies

\[ \lambda x - y - \lambda x - x = -y - \lambda y - x + \lambda y, \]

whence

\[ y + \lambda x - y - \lambda x = -\lambda y - x + \lambda y + x, \]

\[ [-y, -\lambda x] = [\lambda y, x], \]

or, after replacing \(-y \) and \(-\lambda x \) by \( y \) and \( x \) respectively:

\[ [y, x] = [I\lambda y, I\lambda^{-1}x]. \quad (2.26) \]

Applying (2.26) to the right-hand side of the same identity, we obtain

\[ [y, x] = [(I\lambda)^2y, (I\lambda^{-1})^2x], \]

\[ [y, x] = [\lambda^2y, \lambda^{-2}x]. \]

But \( \lambda^3 = (L^{-1})^3 = L^{-3} = 1, \) so,

\[ [y, x] = [\lambda^{-1}y, \lambda x]. \quad (2.27) \]

\[ ^{17}\text{The explanatory remarks have been added by the Editors.} \]
From the equality (2.26) we also get

$$[Iy, Ix] = [\lambda y, \lambda^{-1} x].$$  (2.28)

Finally, applying (2.27) to the right-hand side of the same identity, we get

$$[y, x] = [\lambda^{-2} y, \lambda^2 x],$$

$$[y, x] = [\lambda y, \lambda^{-1} x].$$  (2.29)

Comparing (2.28) and (2.29), we have

$$[Iy, Ix] = [y, x],$$

or, in expanded form,

$$-Iy - Ix + Iy + Ix = -y - x + y + x,$$

$$y + x - y - x = -y - x + y + x,$$

whence it follows that

$$x + y + y + x - y - x = y + x,$$

$$x + x + y + y + x = x + y + x + x + y,$$

$$2x + 2y + 2x = x + y + x + x + y + x = 2(x + y + x)$$

which proves (2.24).

**Remark 5.** If $Q(\cdot)$ is metabelian then the identity (2.24) is satisfied automatically.

**Example** of a $\Pi$-quasigroup which satisfies an identity of type $T_1$.

Let $x \cdot y = x + y$, where $Q(\cdot)$ is a group of exponent 3, in additive notation $3x = 0$. Here, evidently, $R = L = 1$.\(^1\) The condition $LI = IL$ holds trivially. The quasigroup $(\cdot)$ has the form: $x \circ y = x - y + x = y - x + y$. The loop $(\oplus)$ is defined by the equality: $x \oplus y = I\lambda^{-1} x + y + I\lambda y = Ix + y + Ix = -x + y - x = -x + y + 2x$. It is known [1] that $(\oplus)$ is a commutative Moufang loop.

\(^{18}\)Editors' Remark: The original text says “Let $(Q, \cdot)$ be a group of exponent 3, in additive notation $3x = 0$. Here, evidently, $R = L = 1$.\)” but this text does not make good sense.
2) II-quasigroups $A = \cdot$ of type $T_2 = [1, 1, l]$. Such quasigroups satisfy the identity

$$x(y \cdot yx) = y.$$ \hfill (2.30)

We suppose that the quasigroup $Q(\cdot)$ has an idempotent element 0 and we consider the $LP$-isotope $x + y = R^{-1}x \cdot L^{-1}y$, where $R = R_0$, $L = L_0$ and so 0 is the identity of the loop $Q(\cdot)$.

Replacing $(\cdot)$ by $(\pm)$ in (2.30), we get

$$Rx + L(Ry + L(Ry + Lx)) = y.$$ \hfill (2.31)

Assume that $Q(\pm)$ is a group and that $RL = LR$. Then (2.31) implies that

$$L(y + L(y + x)) = -RL^{-1}x + R^{-1}y.$$ If $y = 0$, then $L^2x = -RL^{-1}x$, whence $L^2 = IRL^{-1}$ and so $R = IL^3$ (where $Ix = x$). We note that $IL = LI$, because $IL = RL^{-1}L = L^{-2}R = LI$. Consequently, the following equality holds in $Q(\pm)$:

$$L(y + L(y + x)) = L^2x + IL^{-3}y.$$ \hfill (2.32)

and (since $x \cdot y = Rx + Ly$) the quasigroup operation $(\cdot)$ can be expressed in terms of $(\pm)$ as follows:

$$x \cdot y = -L^3x + Ly.$$ \hfill (2.33)

It is easy to check the converse statement. The quasigroup $Q(\cdot)$ defined by (2.33), where $(\pm)$ is a group and $L$ is a permutation satisfying the identity (2.32), will be a II-quasigroup of type $[1, 1, l]$, i.e. in this quasigroup the identity (2.30) will be satisfied. We have

$$x(y \cdot yx) = -L^3x + L(-L^3y + L(-L^3y + Lx))$$
$$= -L^3x + L^2(Lx) + IL^{-3}(-L^3y)$$
$$= -L^3x + L^3x + IL^{-3}IL^3y = y.$$ Put $x = 0$ in (2.32) we get $L(y + Ly) = IL^{-3}y$, whence

$$1 + L^4 + L^5 = 0.$$ If $L$ is an automorphism of the group $Q(\cdot)$, then (2.32) implies that $Ly + L^2y + L^2x = L^2x + IL^{-3}y$ and, from above, we also have $Ly + L^2y = IL^{-3}y$ whence $IL^{-3}y + L^2x = L^2x + IL^{-3}y$, and so $y + x = x + y$: that is, in this case the group $Q(\cdot)$ is abelian.
3) II-quasigroups $A = (\cdot) \text{ of type } T_4 = [1, 1, lr]$.

Such a quasigroup $(Q, \cdot)$ is a Stein quasigroup in which the identity $x \cdot xy = yx$ holds. In [3] it was proved that, if $Q(\cdot)$ is isotopic to a group, then this group is metabelian.

4) II-quasigroups $A = (\circ) \text{ of type } T_6 = [1, l, lr]$.

In such quasigroups the identity

$$x \circ (y \circ x) = (y \circ x) \circ y$$

(2.34)

holds. From (2.34) it follows at once that $Q(\circ)$ is idempotent. Indeed, let $y = f_x$. Then, $x \circ (f_x \circ x) = (f_x \circ x) \circ f_x$ or $x \circ x = x \circ f_x$ and so $x = f_x$. Thus, $y = f_x \Rightarrow x = f_x$ and so $x \circ x = f_x \circ x$ for every choice of $x$: that is, $x \circ x = x$ for every choice of $x$.

Let $x \cdot y = R_1^{-1}x \circ L_1^{-1}y$, where $1$ is a fixed element of $Q$. It is clear that $1$ is the identity of the loop $Q(\cdot)$. After transformation of $\circ$ into $\cdot$, the equality (2.34) takes the form

$$Rx \cdot L(Ry \cdot Lx) = R(Ry \cdot Lx) \cdot Ly,$$  

(2.35)

where $R = R_1$, $L = L_1$. By replacing $y$ and $x$ by $L^{-1}y$ and $L^{-1}x$ respectively in (2.35), we obtain

$$RL^{-1}x \cdot L(RL^{-1}y \cdot x) = R(RL^{-1}y \cdot x) \cdot y$$

or

$$\varphi x \cdot L(\varphi y \cdot x) = R(\varphi y \cdot x)y,$$  

(2.36)

where $\varphi$ denotes the mapping $RL^{-1}$.

Further we assume that $Q(\cdot)$ is a group. Let $\varphi y \cdot x = z$. Then $x = I\varphi y \cdot z$ (where $Iu = u^{-1}$) and (2.36) implies that

$$\varphi(I\varphi y \cdot z)Lz = Rz \cdot y, \quad \varphi(I\varphi y \cdot z) = RzyILz,$$

$$\varphi(yz) = Rz \cdot \varphi^{-1}y \cdot ILz.$$  

(2.37)

If $z = 1$, then $\varphi = \varphi^{-1}I$ and so $\varphi^2 = I$ and the equality (2.37) takes the form

$$\varphi(yz) = Rz \cdot \varphi y \cdot ILz.$$  

(2.38)

It is easy to observe that (2.38) and $\varphi^2 = I$ together imply (2.37).
We determine $\varphi(xyz)$ in two ways:

$$\varphi(xyz) = \varphi(xy \cdot z) = Rz\varphi(xy)ILz = RzRy\varphi xILyILz,$$

$$\varphi(xyz) = \varphi(x \cdot yz) = R(yz)\varphi xIL(yz).$$

Consequently,

$$RzRy\varphi xILyILz = R(yz)\varphi xIL(yz),$$

whence, replacing $\varphi x$ by $x$, we obtain

$$(IR(yz)RzRy)x = x(IL(yz)LzLy). \quad (2.39)$$

Putting $x = 1$, we deduce that the equality (2.39) implies

$$IR(yz)RzRy = IL(yz)LzLy = C^{-1}(y,z), \quad \text{say.}$$

Then (2.39) implies that $C^{-1}(y,z)$ belongs to the centre $Z$ of $Q(\cdot)$. So,

$$R(yz) = RzRyC(y,z), \quad L(yz) = LzLyC(y,z). \quad (2.40)$$

Now we show that $R$ and $L$ commute. Putting $x = 1$ and $y = 1$ in turn into (2.36), we deduce that

$$L\varphi y = R\varphi y \cdot y, \quad \varphi x \cdot Lx = Rx,$$

whence $Ly = Ry \cdot \varphi^{-1}y$ or $\varphi^{-1}y = IRy \cdot Ly$ and $\varphi x = RxILx$. But $I\varphi = \varphi^{-1}$, so $I(Rx \cdot ILx) = IRx \cdot Lx$. That is, $Lx \cdot IRx = IRx \cdot Lx$ or

$$Rx \cdot Lx = Lx \cdot Rx = x \quad (2.41)$$

because $x = x \circ x = Rx \cdot Lx$ from the definition of the operation $(\cdot)$. Replacing $x$ by $L^{-1}x$ in (2.41), we obtain $RL^{-1}x \cdot x = L^{-1}x$, or $\varphi x \cdot x = L^{-1}x$. Also, from above, $\varphi x = Rx \cdot ILx = ILx \cdot Rx$ because $Lx$ and $Rx$ commute. On the other hand, the equality $RL^{-1}x \cdot x = L^{-1}x$ implies that

$$L^{-1}Rx = RL^{-1}Rx \cdot Rx = (RL^{-1})^2Lx \cdot Rx = \varphi^2Lx \cdot Rx = ILx \cdot Rx.$$ 

Consequently, $\varphi x = L^{-1}Rx$ or $RL^{-1} = L^{-1}R$, whence $RL = LR$.

**Theorem 4.** Suppose that the mappings $R$ and $L$ of a group $Q(\cdot)$ satisfy the conditions (2.40) and (2.41), where $C(x,y)$ is in the centre $Z$ of $Q(\cdot)$. Then the isotope $Q(\circ)$, where $x \circ y = Rx \cdot Ly$, is a $\Pi$-quasigroup of type $[1,l,lr]$. 

Proof. To prove this theorem, we compute the left and right sides of the equality (2.34) using (2.40).

\[ x \circ (y \circ x) = Rx \cdot L(Ry \cdot Lx) = RxL^2xRLyC(Ry, Lx), \]

\[ (y \circ x) \circ y = R(Ry \cdot Lx) \cdot Ly = RLxR^2yC(Ry, Lx)Ly. \]

But \( RxL^2x = LRx \) and \( R^2yLy = RLy \) as we now show.

\[ RxL^2x = RxiR^2x = RxiR(Rx) = L(Rx) = LRx, \]

\[ R^2yLy = IL^2yLy = IL(Ly)Ly = RLy. \]

Here we used the equalities \( R^2 = IL^2 \) (which follows from \( \varphi^2 = I \) and \( RL^{-1} = L^{-1}R \)) and \( x \cdot IRx = Lx \), \( ILx \cdot x = Rx \) (the latter identities being a consequence of \( Lx \cdot Rx = x \)). Thus,

\[ x \circ (y \circ x) = LRxLRyC(Ry, Lx), \]

\[ (y \circ x) \circ y = RLxRLyC(Ry, Lx), \]

whence, because \( RL = LR \), we obtain \( x \circ (y \circ x) = (y \circ x) \circ y \). 

Now we prove the following result.

Theorem 5. If a group is isotopic to a \( \Pi \)-quasigroup of type \([1, l, lr]\), then it is metabelian.

Proof. For the proof we use the equality (2.38): namely,

\[ \varphi(yz) = Rz\varphi yILz. \]

But \( \varphi = RL^{-1} \). We showed above that \( RL = LR \) and \( IL = R^2L^{-1} \), where the last equality follows from \( R^2 = IL^2 \). So, (2.38) can be written as follows:

\[ L^{-1}R(yz) = Rz \cdot L^{-1}Ry \cdot L^{-1}R^2z, \]

\[ R(yz) = L(Rz \cdot L^{-1}Ry \cdot L^{-1}R^2z). \] (2.42)

Next we determine \( L(uvw) \) using the second equality of (2.40):

\[ L(uvw) = L(uw \cdot w) = LwL(uv)C(uv, w) \]

\[ = LwLvLuC(u, v)C(uv, w) = LwLvLuD(u, v, w), \]

where \( C(u, v)C(uv, w) = D(u, v, w) \in Z \), the centre of the group \( Q(\cdot) \).
Consequently, from (2.42) and the first equality of (2.40), we obtain
\[
RzRyC(y, z) = L(L^{-1}R^2z)L(L^{-1}Ry)L(Rz)D(Rz, L^{-1}Ry, L^{-1}R^2z),
\]
\[
RzRyC(y, z) = R^2zRyLRzD(Rz, L^{-1}Ry, L^{-1}R^2z),
\]
\[
RzRy = R^2zRyLRzK(y, z),
\]
where \( K(y, z) = D(Rz, L^{-1}Ry, L^{-1}R^2z)C^{-1}(y, z) \in Z. \)

Replacing \( Rz, Ry \) by \( z, y \) respectively in (2.43), we get
\[
zy = Rz \cdot y \cdot Lz \cdot K(R^{-1}y, R^{-1}z),
\]
where \( K(R^{-1}y, R^{-1}z) \in Z. \) But \( z = Rz \cdot Lz \) from (2.41), so
\[
Rz \cdot Lz \cdot y = Rz \cdot y \cdot Lz \cdot K(R^{-1}y, R^{-1}z),
\]
\[
Lz \cdot y = y \cdot Lz \cdot K(R^{-1}y, R^{-1}z),
\]
\[
z \cdot y = y \cdot z \cdot K(R^{-1}y, R^{-1}L^{-1}z),
\]
where \( K(R^{-1}y, R^{-1}L^{-1}z) \in Z. \) So, (2.44) implies that \( [z, y] = K(R^{-1}y, R^{-1}L^{-1}z), \) i.e. \( [z, y] \in Z, \) which means that \( Q(\cdot) \) is metabelian.  

5) II-quasigroups \( A = (\cdot) \) of type \( T_{10} = [1, lr, l]. \)

In such quasigroups
\[
xy \cdot yx = y.
\]
We remark at once that these quasigroups and also quasigroups satisfying the identity \( xy \cdot yx = x \) are difficult to characterize completely even if we suppose that they are isotopic to groups.

We assume that there is an idempotent element 0 in the quasigroup \( Q(\cdot) \) and we consider the isotope \( x + y = R_0^{-1}x \cdot L_0^{-1}y, \) whence \( x \cdot y = Rx + Ly \) (where \( R = R_0, L = L_0 \) and \( 0 \cdot 0 = 0 \) is the identity of the loop \( Q(+). \)). Replacing the operation \( \cdot \) by \( + \) in (2.45), we get
\[
R(Rx + Ly) + L(Ry + Lx) = y.
\]
Putting \( x = 0 \) and \( y = 0 \) in turn into (2.46), we obtain \( RLy + LRy = y \) and \( R^2x + L^2x = 0, \) or
\[
RL + LR = 1,
\]
\[
R^2 + L^2 = 0.
\]

\(^{19}\)The Editors have simplified and made unambiguous the latter part of this proof by a change of notation for the centre elements and by inserting missing symbols denoting the operation \( \cdot. \).
Let us suppose now that \( Q(+) \) is a group and that \( R \) and \( L \) are automorphisms of this group. Then it follows from (2.46) that

\[
R^2x + R Ly + LRy + L^2x = y,
\]

whence, by (2.47), we obtain

\[
R^2x + y + L^2x = y,
\]
or

\[
y + L^2x = -R^2x + y.
\]

But (2.48) implies that \(-R^2x = L^2x\), and consequently we have

\[
y + L^2x = L^2x + y;
\]

that is, in this case the group \( Q(+) \) is abelian.

Now, we strengthen our suppositions. Suppose that \( RL = LR \), then (2.47) implies that \( 2RL = 1 \), \( 2RLx = x \), \( 2x = L^{-1}R^{-1}x \), i.e. the mapping

\[
\tau : x \to 2x
\]
is a permutation of the set \( Q \), \( \tau = L^{-1}R^{-1} \).

We determine another connection between \( R \) and \( L \). It is evident that

\[
R(2x) = 2Rx,
\]
hence \( R(2LR) = R \) is equivalent to \( 2R^2L = R \). But \( R^2 = -L^2 \), whence \( 2(-L^2)L = R \), \( R = -2L^3 \). By symmetry, \( L = -2R^3 \).

Moreover, we have \( R^2 + L^2 = R^2 + (-2R^3)^2 = R^2 + 4R^6 = 0 \), whence it follows that \( 4R^4 = -1 \). Analogously, \( 4L^4 = -1 \). We obtain the same connection using the three relations \( 2RL = 1 \), \( L = -2R^3 \), \( R = -2L^3 \) alone.

The following proposition is true: if \( Q(+) \) is an abelian group having \( L \) as an automorphism and if \( 4L^3 = -1 \) and \( x \cdot y = -2L^3x + Ly \), then \( Q(+) \) is a \( \Pi \)-quasigroup of type \([1, lr, l]\):

\[
x y \cdot y x = -2L^3(-2L^3x + Ly) + L(-2L^3y + Lx)
= 4L^6x - 2L^4y - 2L^4y + L^2x = L^2(1 + 4L^4)x - 4L^4y = y.
\]

**Example** of a \( \pi \)-quasigroup of type \([1, lr, l]\). Let \( Q(+, \cdot) \) be the field of complex numbers. We define \( x \circ y = a(x + iy) \), where \( a^2 = -\frac{1}{2}i \). Then \( Q(\circ) \) is a \( \Pi \)-quasigroup of type \([1, lr, l]\). Indeed, we have

\[
(x \circ y) \circ (y \circ x) = a(a(x + iy) + ia(y + ix))
= a^2(x + iy + iy - x) = 2a^2iy = y.
\]
Here \( Rx = ax, \ Lx = aix. \)

6) II-quasigroups \( A = (\cdot) \) of type \( T_8 = [1, rl, lr] \).

In such quasigroups the identity

\[
xy \cdot y = x \cdot xy. \tag{2.49}
\]

is satisfied. Let \( x + y = R_a^{-1}x \cdot L_b^{-1}y \). Then \( x \cdot y = Rx + Ly \), where \( R = R_a \), \( L = L_b \). Replacing the operation \( (\cdot) \) by \((+)\) in (2.49), we get

\[
R(Rx + Ly) + Ly = Rx + L(Rx + Ly),
\]

whence

\[
R(x + y) + y = x + L(x + y). \tag{2.50}
\]

Putting \( y = 0 \) (where \( 0 = ba \) is the identity of the loop \( Q(+) \)), we obtain \( Rx = x + Lx \). This together with (2.50) imply that

\[
[x + y + L(x + y)] + y = x + L(x + y),
\]

and so

\[
y + L(x + y) + y = L(x + y).
\]

provided that \((Q, +)\) is a group.

Replacing \( L(x + y) \) by \( x \) we have

\[
y + x + y = x.
\]

From this it follows that \( 2y = 0 \) and \( x + y = y + x \). Therefore, we have proved the following proposition.

**Theorem 6.** If a group is isotopic to a II-quasigroup of type \([1, rl, lr]\), then it is an abelian group of exponent two. \( \square \)

The equality \( Rx = x + Lx \) shows that \( L \) is a complete mapping.\(^{20}\) We show that, if \( Q(+) \) is an abelian group of exponent two and \( L \) is a complete

---

\(^{20}\)Here, 0 is an idempotent element of the quasigroup \((Q, \cdot)\) and \( R_0 x = x \circ 0 = ax, 0, \ L_0 x = 0 \circ x = 0 + aix.\)

\(^{\text{a}}\)A permutation \( \varphi \) is called a complete mapping for a quasigroup \( Q(\cdot) \) if there exists another permutation \( \varphi' \) of the set \( Q \) such that \( x \cdot \varphi(x) = \varphi'(x) \) for all \( x \in Q.\)

Editors’ Remark: The mapping \( \varphi' \) is called the orthomorphism corresponding to \( \varphi.\)
mapping, then \( Q(\cdot) \), where \( x \cdot y = x + Lx + Ly \), is a \( \Pi \)-quasigroup of type \([1, rl, lr]\). Indeed,

\[
x \cdot xy = x + Lx + L(xy) = x + Lx + L(x + Lx + Ly),
\]

\[
xy \cdot y = xy + L(xy) + Ly = x + Lx + Ly + L(x + Lx + Ly) + Ly
= x + Lx + L(x + Lx + Ly).
\]

Consequently, \( x \cdot xy = xy \cdot y \).

We end this Section by showing that an arbitrary group of exponent two has a complete mapping. For this purpose, we remark that any finite group \( Q \) of exponent two can be presented as a set of \( n \)-tuples \( \{\bar{a} = (a_1, a_2, \ldots, a_n)\} \), where \( a_i \in \{0, 1\} \) - the cyclic group of order two. It is clear that \( 2\bar{a} = \bar{0} \) and that \( \bar{0} = (0, 0, \ldots, 0) \). We define the mapping \( L \) on \( Q \) by putting

\[
L\bar{a} = (a_1 + a_2, a_2 + a_3, \ldots, a_{n-1} + a_n, a_1).
\]

It is evident that \( L \) produces a permutation of the set \( Q \). We determine \( R \), where \( R\bar{a} = \bar{a} + L\bar{a} \):

\[
R\bar{a} = (a_1, a_2, \ldots, a_{n-1}, a_n) + (a_1 + a_2 + a_3 + \ldots, a_{n-1} + a_n, a_1)
= (a_1 + a_1 + a_2, a_2 + a_2 + a_3, \ldots, a_{n-1} + a_n + a_n, a_n + a_1)
= (a_2, a_3, \ldots, a_n, a_n + a_1).
\]

Clearly, \( R \) is a permutation of the set \( Q \) and so \( L \) is a complete mapping. Therefore, we have proved that any finite group of exponent two is isotopic to a \( \Pi \)-quasigroup of type \([1, rl, lr]\).

It remains to consider the last case.

7) \( \Pi \)-quasigroups \( A = (\cdot) \) of type \( T_{11} = [1, lr, rl] \).

In such quasigroups the identity

\[
xy \cdot yx = x. \tag{2.51}
\]

holds. Very little can be said about these quasigroups apart from the fact that they are similar to the \( \Pi \)-quasigroups of type \([1, lr, l]\). Assuming that \( Q(\cdot) \) has an idempotent element \( 0 \) then, by putting \( R_0 = R, L_0 = L \) and replacing the operation \( (\cdot) \) by \( (+) \) in (2.51), where \( x + y = R^{-1}x \cdot L^{-1}y \), we obtain the equality

\[
R(Rx + Ly) + L(Ry + Lx) = x,
\]
whence it follows that
\[ RL + LR = 0, \]
\[ R^2 + L^2 = 1. \]  
(2.52)
If we suppose also that \( Q(+) \) is a group and that \( R \) and \( L \) are automorphisms of this group then, contrary to the situation for quasigroups of type \( T_{10} = [1.r, l] \), the mapping \( R \) cannot be expressed in terms of \( L \). However, we can construct examples of groups \( Q(+) \) with automorphisms \( R \) and \( L \) satisfying (2.52). One such example is the quasigroup defined by Table 2.

§3. Some remarks

1. From Table 6 it follows that, when a quasigroup \( Q(\cdot) \) satisfies some minimal identity from that Table, then \( \cdot \) is orthogonal to one or more parastrophes of \( \cdot \). So, we have a natural question: Under which systems of identities from Table 1 will a quasigroup \( \cdot \) be orthogonal to all of its parastrophes?

First we give such a table (Table 7).

<table>
<thead>
<tr>
<th>No.</th>
<th>Orthogonality</th>
<th>No of identity in Table 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>1 ( \perp ) r</td>
<td>1, 2, 3, 6</td>
</tr>
<tr>
<td>2.</td>
<td>1 ( \perp ) l</td>
<td>6</td>
</tr>
<tr>
<td>3.</td>
<td>1 ( \perp ) rl</td>
<td>2, 4</td>
</tr>
<tr>
<td>4.</td>
<td>1 ( \perp ) lr</td>
<td>4</td>
</tr>
<tr>
<td>5.</td>
<td>1 ( \perp ) s</td>
<td>3, 5, 7</td>
</tr>
</tbody>
</table>

Table 7

From the table, we see that the identities 4 and 6 must both be satisfied in order to ensure the orthogonalities 1 \( \perp \) l, 1 \( \perp \) lr, i.e. the identities \( xy \cdot x = y \cdot xy \) and \( xy \cdot y = x \cdot xy \) must both be satisfied. To guarantee the remaining orthogonalities we have to take the following combinations: (3, 4, 6), (5, 4, 6) or (7, 4, 6), i.e. we need to add one of the identities \( x \cdot xy = yx \), \( yx \cdot xy = x \) or \( xy \cdot yx = x \) to the previous two identities.

We shall consider each case separately.

1st case: (3, 4, 6).

We have the identities
\[ x \cdot xy = yx, \quad xy \cdot x = y \cdot xy, \quad xy \cdot y = x \cdot xy. \]  
(3.1)
If we put \( u = xy \) and \( v = yx \), the identities (3.1) take the form

\[
xu = v, \quad ux = yu, \quad uy = xu.
\]

We calculate \( v \cdot xv \) in two ways:

\[
v \cdot xv = (yx)(x \cdot yx) = (yx)(yx \cdot y) = y \cdot yx = xy = u.
\]

Here we used the identities 3 and 4.

\[
v \cdot xv = (yx)(x \cdot yx) = (x \cdot xy)[x(x \cdot xy)] = (xu)(x \cdot xu) = (x \cdot xu)x = xu \cdot x = u \cdot ux = xu.
\]

Here we used all the identities from (3.1). Comparing the results obtained, we get \( xu = u \). But Stein’s identity \( x \cdot xy = yx \) implies idempotency. (Putting \( x = y \) in this identity, we obtain \( x \cdot xx = xx \), whence \( x^2 = x \).) So the equality \( xu = u \) can be re-written in the form \( xu = uu \). Therefore \( u = x \); that is, \( xy = x = xx \) and so \( y = x \). Thus, the identities (3.1) are all satisfied only in a one-element set.

**2nd case:** (5, 4, 6).

We have

\[
yx \cdot xy = x, \quad xy \cdot x = y \cdot xy, \quad xy \cdot y = x \cdot xy.
\]  

(3.2)

The equality \( x = y \) follows directly since

\[
x = (xy \cdot x)(x \cdot xy) = (y \cdot xy)(xy \cdot y) = xy,
\]

and, because \( x \) and \( y \) independently may be any elements from \( Q \), the equality \( x = xy \) implies that all elements of \( Q \) are equal. So, in this case also, the identities from (3.2) hold simultaneously only in a one-element quasigroup.

**3rd case:** (7, 4, 6).

We have the identities

\[
xy \cdot yx = x, \quad xy \cdot x = y \cdot xy, \quad xy \cdot y = x \cdot xy.
\]

Here the proof is almost an exact copy of that above. We have

\[
x = (x \cdot xy)(xy \cdot x) = (xy \cdot y)(y \cdot xy) = xy,
\]

and so on.
So, we have proved

**Theorem 7.** A Π-quasigroup $Q(A)$ in which minimal identities (of specified types) hold cannot be orthogonal to all of its parastrophes.

On the other hand, it is easy to construct a quasigroup $A$ such that $A \perp A$ for any specified $\sigma, \tau \in S_3$. Here is an example: $A(x, y) = 2x + 3y$, where $Q(\cdot, \cdot)$ is the field of rational numbers. The parastrophes of $A$ are as follows:

\[
\begin{align*}
A^{-1}(x, y) &= \frac{1}{3}(-2x + y), & -1A(x, y) &= \frac{1}{2}(x - 3y), \\
-1(A^{-1}) &= -\frac{1}{2}(3x - y), & (-1A)^{-1}(x, y) &= -\frac{1}{3}(-x + 2y), \\
A^*(x, y) &= 3x + 2y.
\end{align*}
\]

Since the determinant of the system of equations $A(x, y) = a$, $A(x, y) = b$ for each pair $\sigma, \tau \in S_3$ is not equal to zero, we have $A \perp A$.

2. The connection between minimal identities and orthogonality suggests the following question: *Are there other identities which give rise to orthogonal parastrophes?*

To obtain a reply to this question, we return to the notion of a minimal nontrivial identity. As was shown earlier, every such identity can be written in the form $ABC = E$ or, more precisely,

\[
A(x, B(x, C(x, y))) = y. 	ag{3.3}
\]

As we remarked earlier, all other minimal nontrivial identities can be transformed to this form. Thus, in particular, the identity:

\[
G[K(x, y), L(x, y)] = x. \tag{3.4}
\]

can be so transformed.

The converse statement is valid too: *an identity of the form (3.3) is equivalent to an identity of the form (3.4).* Indeed, (3.3) implies that

\[
-1A(y, B(x, C(x, y))) = x. \tag{3.5}
\]

Let $C(x, y) = z$, then $y = C^{-1}(x, z)$, whence (3.5) becomes

\[
-1A(C^{-1}(x, z), B(x, z)) = x, \tag{3.6}
\]

and so we obtain an identity of the form (3.4).
We deduce that

**Lemma 3.** If the quasigroups $G$, $K$, $L$ are connected by the identity (3.4), then $K \perp L$.\(^{21}\)

*Proof.* Indeed, comparing (3.6) and (3.4) we can write $G = -A$, $K = C^{-1}$ and $L = B$. Hence $A = -G$, $B = L$, $C = K^{-1}$ and the equality $ABC = E$ takes the form $-GLK^{-1} = E$. Then $L \perp K$ follows from Lemma 1. \(\square\)

Using the notation of §0, the identity (3.4) can be written in the form $G\bar{\theta} = F$ or $G(K, L) = F$, where $\bar{\theta} = (K, L)$, because $G\bar{\theta}(x, y) = G(K, L)(x, y) = G[K(x, y), L(x, y)] = x$.

We also have the following result:

**Lemma 4.** If $K, L$ are orthogonal quasigroups, then there exists a unique quasigroup $G$ such that $G(K, L) = F$.

*Proof.* Indeed, let $K \perp L$, then $\bar{\theta} = (K, L)$ is a permutation of the set $Q^2$. For $\bar{\theta}$ there exists an inverse permutation $\bar{\theta}^{-1} = (G, H)$, where the operations $G$ and $H$ must be quasigroups by the theorem of §0. Furthermore, we have $\bar{\theta}^{-1}\bar{\theta} = (G, H)\bar{\theta} = (G\bar{\theta}, h\bar{\theta}) = \bar{\varepsilon}$, where $\bar{\varepsilon}$ is the identity permutation of $Q^2$. But $\bar{\varepsilon} = (F, E)$, thus $(G\bar{\theta}, H\bar{\theta}) = (F, E)$, whence it follows that $G\bar{\theta} = F$ or $G(K, L) = F$. \(\square\)

Next we show that there exist identities of length greater than five with the required property. Suppose that a quasigroup $Q(\cdot, \setminus, /)$ is given and let $f(u, v)$ be an arbitrary word of length at least two in this quasigroup. Further, let $^\sigma A, ^\tau A$ be two parastrophes of the quasigroup $(\cdot) = A$. Consider the identity

$$f(^\sigma A(x, y), ^\tau A(x, y)) = x. \quad (3.7)$$

The word $f(u, v)$ defines some binary operation. Let $^\sigma A = B$. Then $x = -1B(B(x, y), y)$. Consequently, the identity (3.7) can be written in the form

$$f(B(x, y), ^\tau A(x, y)) = -1B(B(x, y), y),$$

$$(-1B)^{-1}(B(x, y), f(B(x, y), ^\tau A(x, y)) = y. \quad (3.8)$$

\(^{21}\)Editors' Note: T. Evans stated this result as an if and only if theorem in his 1975 paper\[13\] and F. E. Bennett \[10\] then used that theorem to obtain his seven identities equivalent to those in Table 1.
We define a subword $f'$ in the following way:

$$f'(u, v) = (-1B)^{-1}(u, f(u, v)),$$

i.e. $f'(u, v)$ also defines a certain binary operation on the quasigroup $Q(\cdot)$. Therefore (3.8) has the form

$$f'(A(x, y), \overline{A}(x, y)) = y. \tag{3.9}$$

Let $(\overline{A}, \overline{A}) = \bar{\theta}$ be a mapping on the set $Q_2$. Equalities (3.7) and (3.9) can be written briefly as:

$$f\bar{\theta} = F, \quad f'\bar{\theta} = E.$$

Consequently, $\bar{\varepsilon} = (F, E) = (f\bar{\theta}, f'\bar{\theta}) = (f, f')\bar{\theta}$ (cf. 8 of §0). The pair $(f, f')$ also defines some mapping $\bar{\varphi}$, so we can write $\bar{\varphi} = (f, f')$. Thus, $\bar{\varphi}\bar{\theta} = \bar{\varepsilon}$. In the case when $Q$ is finite, $Q_2$ is finite too, and then $\bar{\varphi}$, $\bar{\theta}$ are permutations of the set $Q_2$. Because $\bar{\theta} = (\overline{A}, \overline{A})$ is a permutation, we obtain $\overline{A} \perp \overline{A}$.

Moreover, because $\bar{\varphi} = (f, f') = \bar{\theta}^{-1}$, $\bar{\varphi}$ also is a permutation, we can apply the theorem in 8 of §0 and deduce that $f$ is a quasigroup.

For instance, let $f(u, v) = (uv)(v \setminus u)$ and let

$$\overline{A}(x, y) = x \setminus y, \quad \overline{A}(x, y) = yx.$$

We obtain the identity

$$[(x \setminus y)(yx)][(yx) \setminus (x \setminus y)] = x.$$

Then $(\setminus) \perp (\cdot)$, where $x \ast y = yx$, and the mapping $A : (u, v) \rightarrow (uv)(v \setminus u)$ will be a quasigroup.

3. When we investigated identities of the above kind taken from the types in Table 1, we attempted to transform them into a particular form: namely, to identities equivalent to the originals but containing only one basic operation $(\cdot)$. In this connection, we make two remarks. In general, besides the identities listed in that table, there are six other minimal nontrivial identities involving only one operation. We list them below (they can be obtained in a simple way):

1) $(xy \cdot x)x = y \ (T_2)$, 2) $(yx \cdot y)x = y \ (T_5)$, 3) $(xy \cdot y)x = y \ (T_2)$,

4) $(yx \cdot x)x = y \ (T_1)$, 5) $x(y \cdot xy) = y \ (T_5)$, 6) $x(x \cdot yx) = y \ (T_2)$.
The identity type from Table 1 which is equivalent to each of the six listed identities is given in parentheses. It is interesting to add that the identities 2) and 5) are parastrophically equivalent to an identity of type $T_6$ having length six. This can be checked directly: the identity $T_6$, i.e. $xy \cdot x = y \cdot xy$ is parastrophically equivalent to an identity of type $T_6 = [1,l,lr]$, i.e. $x(x/(y/x)) = y$ which is equivalent to the identity $y/(x/(y/x)) = x$. Replacing $(/)$ by $(*)$ and then putting $x*y = y*x$, i.e. applying parastrophic equivalence, we obtain $y \ast (x \ast (y \ast x)) = x$, that is, $(xy \cdot x)y = x$, which is exactly the identity 2). $^b$

In connection with the above, we should make the following (second) remark. The identity $T_6$, i.e. $xy \cdot x = y \cdot xy$, is not minimal in our sense because it has length six. But it is equivalent to the identity $x(x/(y/x)) = y$, which is minimal. It is easy to see that, if we have an identity of the form

$$f_1(x,y,z) = f_2(x,y,z),$$

where $z = xy$, and if the number of occurrences of $x$ (or $y$) is smaller than the number of occurrences of $z = xy$ then, after replacing $x$ by $z/y$ in the first case or $y$ by $x \backslash z$ in the second case, we obtain an identity of shorter length. For example, in the identity $T_6$ (i.e. $xy \cdot x = y \cdot xy$) which has length six, the elements $x$ and $y$ occur only once while the subword $z = xy$ is repeated twice. But, putting $z/y$ instead of $x$, we obtain the identity $z(z/y) = yz$ which has length five.

4. The identities implying orthogonality of parastrophes which are considered above involve only two variables. This raises the question: Are there identities containing more than two variables which imply the orthogonality of parastrophes of a given quasigroup? We show that such identities exist. A general method of constructing such identities is the following. Let $D(x,y) = y$ be a minimal nontrivial identity which holds in the quasigroup $Q(\cdot)$, i.e. $D = ABC$, where $A$, $B$, $C$ are parastrophes of the quasigroup $(\cdot)$. Consider the following identity $w_1 = w_2$, where $w_1$ (or $w_2$) has the form

$$w_1 = \ldots D(u,v) \ldots,$$

where $u, v$ are some subwords. The dots denote variables, parentheses and operation symbols which have been omitted, while $D$ denotes the product

$^b$In obtaining such identities, we considered also identities of the form $(xy \cdot x)y = y$ for example, but such ones can be omitted because, for instance, the example given here is equivalent to the identity $xy \cdot x = y/y$, which is trivial according to our definition since it has a subword of the form $A(y,y)$. 
ABC, where $A$, $B$, $C$ are parastrophes of the operation $(\cdot)$. We assume further that the subword $u$ contains the free element $x$ exactly once and that the subword $v$ contains the free element $y$ exactly once. Moreover, we suppose that $x$ and $y$ do not appear elsewhere in $w_1$ and that the free element $y$ appears exactly once in $w_2$.

We make a retraction of all elements except $x$ and $y$ in the identity $w_1 = w_2$, i.e. we replace all elements except $x$ and $y$ by constant elements of $Q$. Then $u$ and $v$ become replaced by $\alpha x$ and $\beta y$ respectively, while $w_1$ and $w_2$ are replaced by $\gamma D(\alpha x, \beta y)$ and $\delta y$ respectively, i.e. we obtain the identity

$$\gamma D(\alpha x, \beta y) = \delta y,$$

which is valid for any $x$ and $y$ in $Q$. Since all these transformations are made in the quasigroup $Q(\cdot)$, $\alpha$, $\beta$, $\gamma$, $\delta$ are permutations of the set $Q$.

Replacing $\alpha x$ and $\beta y$ by $x$ and $y$, we get

$$\gamma D(x, y) = \delta \beta^{-1} y,$$

whence we obtain $\beta \delta^{-1} \gamma D(x, y) = y$ or

$$\varphi D(x, y) = y,$$  \hspace{1cm} (3.10)

where $\varphi = \beta \delta^{-1} \gamma$. More precisely, because $D = ABC$, the equality (3.10) can be written as

$$\varphi A(x, B(x, C(x, y))) = y.$$  \hspace{1cm} (3.11)

Let us define the operation $A'$ by $A'(x, y) = \varphi A(x, y)$. Then (3.11) can be written briefly in the form $A'BC = E$, which means that $B \perp C^{-1}$.

Example. Consider the identity

$$(zx)(zx)(zx \cdot ty) = z^2(zy \cdot t).$$  \hspace{1cm} (3.12)

We may choose $zx$ and $ty$ as the subwords $u$ and $v$. The left side takes the form $w_1 = u(u \cdot uv)$. Replacing $z$ and $t$ by fixed elements $\alpha$ and $\beta$, we obtain the identity $\alpha x(\alpha x(\alpha x \cdot \beta y)) = \gamma y$, whence, replacing $\alpha x$ by $x$ and $\beta y$ by $y$, we get $x(x \cdot xy) = \gamma \beta^{-1} y$ or $\beta \gamma^{-1} [x(x \cdot xy)] = y$. If $A = (\cdot)$ and $A' = \varphi A$, where $\varphi = \beta \gamma^{-1}$, and $\varphi A$ is defined by $(\varphi A)(x, y) = \varphi A(x, y)$, then $A'AA = E$, i.e. $A \perp A^{-1}$.

We remark that quasigroups satisfying the identity (3.12) do exist. For example, an abelian group $Q(\cdot)$ of exponent three (i.e. $x^3 = 1$ for all $x \in Q$) satisfies (3.12).
Nontrivial quasigroups (ones with more than one element) satisfying specified identities obtained in the above way do not always exist. An example of such an identity is

\[(x \cdot xy)z = (xy \cdot y)(zt). \tag{3.13}\]

Here, the identity \(D(x, y) = y\) is some identity of type \(T_8\), i.e. \(x((y/x)x) = y\) (cf. Table 1), the derived form of which is \(x \cdot xy = xy \cdot y\). In other words, by changing some of the operations in (3.13) to parastrophes, it can be transformed\(^{22}\) to \(\{x((y/x)x)\}z = y \cdot zt\), which is the form wanted.

However, if we put \(x = f_y\) in (3.13), we get \(yz \cdot t = y^2 \cdot zt\). Replacing \(z\) by \(y\) and then cancelling \(y^2\) gives the equality \(t = yt\), which is valid for all \(y\) and \(t\) in \(Q\). But in a nontrivial quasigroup such an identity is impossible.

5. In this last subsection, we formulate some questions:

1. In §2, we studied II-quasigroups which are isotopic to groups. For II-quasigroups satisfying identities of types \(T_2\), \(T_{10}\) and \(T_{11}\), we were unable to obtain a complete answer. Therefore, we pose the following problem: **Find a complete characterization of groups isotopic to quasigroups which satisfy one of the identities \(x(y \cdot yx) = y\), \(xy \cdot yx = y\) and \(xy \cdot yx = x\).**

2. The following question generalizes that raised in the first subsection of this Section: **Under which systems of identities will a quasigroup \((Q, \cdot)\) be orthogonal to all of its parastrophes?**

3. In the second subsection of this Section, we constructed identities of arbitrary length containing two free elements which guarantee the orthogonality of two parastrophes. **Prove that any identity involving two free elements which guarantees the orthogonality of at least two parastrophes of the quasigroup \(Q(\cdot)\) has the form described in that subsection.**

4. Finally, we pose the general problem: **Describe all identities which, when satisfied in a quasigroup \(Q(\cdot)\), guarantee the orthogonality of some parastrophes of the given quasigroup.**

In place of this, probably, we should seek to solve a more restricted problem: namely, **Do there exist identities with two free elements which imply the orthogonality of some parastrophes but which do not have retracts?** (cf. subsection 4 of this Section)

\(^{22}\)We have \(x((y/x)x) = y\). Put \(y/x = u\) and \(u \setminus x = v\). Then \(y = ux\) and \(x = uv\) so \(uv \cdot v = y = u \cdot uv\). Since (3.13) can be written as \([(u \cdot uv)v]z = (uv \cdot v)(zt)\) by changing the variables, it is equivalent to \(yz \cdot t = y \cdot zt\) or \(((x((y/x)x))z)t = y \cdot zt\) which is the form claimed.
